Chapter 1
Preface

1.1 Overview

The primary objective of this document is to define the functionality of the MPC5744P microcontroller for use by software and hardware developers. The MPC5744P Qorivva microcontroller is based on the Power Architecture® developed by Freescale. The MPC5744P is a SafeAssure solution.

As with any technical documentation, it is the reader's responsibility to ensure he or she is using the most recent version of this document.

To locate any published errata or updates for this document, visit the Freescale Web site at http://www.freescale.com.

1.2 Device versions

This release of this document describes the functionality and programming model of the device intended for production.

The device has these part numbers: MPC5744P, MPC5743P, MPC5742P, and MPC5741P. The parts differ with regard to flash memory and system RAM sizes. This document uses MPC5744P as the generic part number.

1.3 Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the MPC5744P device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

1.4 Document organization

This document includes two major sets of chapters:

- Chapters in the first set describe the device as a whole or device-specific information.
- Chapters in the second set describe the functionality of the individual modules on the device. These chapters are organized into the following groups:
    - Core and system modules
    - Clocking modules
    - Memories and memory interfaces
    - Motor control modules
    - Timers
    - Communication interfaces
    - Reset and boot modules
    - Power management modules
    - Debug
    - Safety modules
    - Other modules

1.5 Conventions

1.5.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*.

1.5.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
`code`	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

1.6 Acronyms and abbreviations

Term	Meaning
AUTOSAR	Automotive Open System Architecture
GPIO	General-purpose I/O

Table continues on the next page...

Term	Meaning
IEEE	Institute for Electrical and Electronics Engineers
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
Mux	Multiplex
Rx	Receive
RTL	Register transfer language
SM	Safety Manual
TBD	To be determined
Tx	Transmit
UART	Universal asynchronous/synchronous receiver transmitter

1.7 References

In addition to this reference manual, the following documents provide additional information on the operation of the MPC5744P:

- IEEE-ISTO 5001-2003 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture
- Power Architecture Book E V1.0 (http://www.freescale.com/files/32bit/doc/user_guide/BOOK_EUM.pdf)

Chapter 2
Introduction

2.1 Overview

The MPC5744P Qorivva microcontroller is based on the Power Architecture® developed by Freescale Semiconductor. It targets chassis and safety applications and other applications requiring a high Automotive Safety Integrity Level (SIL). The MPC5744P is a SafeAssure solution.

2.1.1 Overall architecture

All devices in this family are built around a safety concept based on delayed lock step, targeting an ISO26262 ASIL-D (Design) integrity level. According to FMEDA analysis, critical components of the microcontroller that must be replicated are the CPU core and DMA controller. Lock step Checking Units are implemented at each output of these blocks to compare the values between the redundant blocks.

In addition, the MPC5744P provides:

- A programmable Fault Collection and Control Unit (FCCU) to monitor the integrity status of the device and provide flexible safe state control.
- End-to-End Error Correcting Code (e2eECC) for improved fault tolerance and detection:
  - All bus masters generate Single Error Correcting and Double Error Detecting (SECDED) code for every bus transaction
  - SECDED covers 64-bit data and 29-bit address
  - ECC is stored in memories on write operations and validated by the master on every read operation

2.1.2 Core features

The host processor core of the MPC5744P is a CPU from the e200 family of compatible Power Architecture cores. The z425n3 dual issue core provides very high efficiency—high performance with minimum power dissipation—and operates at a maximum frequency of 200MHz.

The processor family implements low-cost versions of the *PowerISA 2.06* architecture. The z425n3 is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general purpose registers (GPRs).

An Embedded Floating-point (EFPU2) Auxiliary Processing Unit (APU) is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed-point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the GPRs.

The z425n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is documented in *PowerISA 2.06*, a separate document. Note that the base PowerISA 2.06 fixed-length 32-bit instruction set is not directly supported.

The z425n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The z425n3 also contains an 8 KB Instruction Cache and a 4 KB Data Cache as well as a Nexus Class 3+ debug module.

A Memory Protection Unit (MPU) is also included which supports protections of various instruction and data memory areas.

The MPC5744P has two e200z4 CPU core complexes running in delayed lock step.

2.1.3 Memory hierarchy

The MPC5744P has a single level of memory hierarchy consisting of 384 KB on-chip SRAM and 64 KB tightly coupled local data SRAM with ECC and 2.5 MB on-chip flash memory including ECC. Both the SRAM and the flash memory can hold instructions and data.

2.1.4 Off-chip communication

Off-chip communication is performed by a suite of serial protocols including FlexRay, CANs, enhanced SPIs (DSPIs), SCIs (LINFlexD), SIPI (via LFAST), Ethernet, and the SENT sensor interface.

2.1.5 I/O control

The System Integration Unit “Lite2” (SIUL2) performs several chip-wide configuration functions. SIUL2 is not software compatible to the SIUL used on Freescale C90 products.

The SIUL2 controls pad configuration and general-purpose input/output (GPIO). External interrupts and reset control are also found in the SIUL2. The internal multiplexer sub-block (IOMUX) provides multiplexing options for the device pins’ output and input paths (for example, daisy chaining the DSPIs and external interrupt signal).

2.1.6 Peripheral set compatibility

The MPC5744P peripheral set is compatible with the MPC5643L, providing high-end electrical motor control capability with very low CPU intervention due to the on-chip Cross Triggering Unit (CTU). For more information, see Compatibility with MPC5643L.

2.1.7 Technology

The MPC5744P is developed with 55 nm embedded flash memory technology, providing a significant performance improvement.

2.2 Target applications

As a SafeAssure solution, the MPC5744P microcontroller targets applications requiring a high Automotive Safety Integrity Level (ASIL), especially:

- Chassis applications
- Electrical Stability Control (ESC)
- Higher-end Electrical Power Steering (EPS)
- Airbag and sensor fusion applications
- Radar applications

A typical aspect of ESC and EPS is the presence of an advanced electrical motor control periphery with special enhancements in the area of pulse width modulations, highly flexible timers, and functional safety. All devices in this family are built around a safety concept based on delayed lock step, targeting an ISO26262 ASIL-D integrity level.

2.3 Features

The following table summarizes the features of the MPC5744P.

Table 2-1. MPC5744P feature summary

Feature	Details
CPU	
Power Architecture	2 x e200z4 in delayed lock step
Architecture	Harvard
Execution speed	0 MHz to 200 MHz (+2% FM)
Embedded FPU	Yes
Core MPU	24 regions
Instruction Set PPC	No
Instruction Set VLE	Yes
Instruction cache	8 KB, EDC
Data cache	4 KB, EDC
Data local memory	64 KB, ECC
System MPU	Yes (16 regions)
Buses	
Core bus	AHB, 32-bit address, 64-bit data, e2e ECC
Internal periphery bus	32-bit address, 32-bit data
Crossbar	
Master x slave ports	4 x 5
Memory—see Table 2-2 for additional details	
Code/data flash memory	**2.5 MB**, ECC, RWW
Data flash memory	Supported with RWW
SRAM	**384 KB**, ECC
Overlay access to SRAM from Flash Memory Controller	Yes
Modules	
Interrupt controller	32 interrupt priority levels, 16 SW programmable interrupts
PIT	1 module with 4 channels
System Timer Module (STM)	1 module with 4 channels
Software Watchdog Timer (SWT)	Yes
eDMA	32 channels, in delayed lock step
FlexRay	1 module with 64 message buffer, dual channel
FlexCAN	3 modules with 64 message buffer

Table continues on the next page...

Table 2-1. MPC5744P feature summary (continued)

Feature	Details
LINFlexD (UART and LIN with DMA support)	2 modules
Clockout	Yes
Fault Control and Collection Unit (FCCU)	Yes
Cross Triggering Unit (CTU)	2 modules
eTimer	3 modules with 6 channels
FlexPWM	2 modules with 4 x (2+1) channels
Analog-to-digital converter (ADC)	4 modules with 12-bit ADC, each with 16 channels (25 external channels including shared channels plus internal channels)
Sine-wave generator (SGEN)	32 point
SPI	4 modules As many as 8 chip selects
CRC Unit	Yes
SENT	2 modules with 2 channels
Interprocessor serial link interface (SIPI)	Yes
Junction temperature sensor	Yes (replicated module)
Digital I/Os	≥ 16
Peripheral register protection	Yes
Ethernet	Yes
Error Injection Module (EIM)	Yes
Supply	
Device Power Supply	3.3 V with external ballast transistor 3.3 V with external 1.25 V low drop-out (LDO) regulator
ADC Analog Reference voltage	3.15 V to 5.5 V
Clocking	
Phase Lock Loop (PLL)	1 x PLL and 1 coupled FMPLL
Internal RC Oscillator	16 MHz
External Crystal Oscillator	8 MHz to 40 MHz
Low power modes	
HALT and STOP	Yes
Debug	
Nexus	Level 3+, MDO and Aurora interface
Package	
LQFP	144 pins, 0.5 mm pitch, 20 mm x 20 mm outline
MAPBGA	257 MAPBGA, 0.8 mm pitch, 14 mm x 14 mm outline
Temperature	
Temperature range (junction)	-40°C to +150°C, option for 165°C
Ambient temperature range (LQFP)	-40°C to +125°C, 135°C option (with 165°C junction option)
Ambient temperature range (BGA)	-40°C to +125°C, 135°C option (with 165°C junction option)

Table 2-2. Flash memory and SRAM sizes of MPC5744P, MPC5743P, MPC5742P, and MPC5741P

Part number	Flash memory	SRAM
MPC5744P	2.5 MB	384 KB
MPC5743P	2.0 MB	256 KB
MPC5742P	1.5 MB	192 KB
MPC5741P	1.0 MB	128 KB

The MPC5744P architecture is based on the Automotive Core Platform (ACP) developed as part of the C55 Template.

This architecture is centered around the scalable e200 family, the AMBA standards, and Freescale’s IP standards.

- AMBA is a 64-bit bus supporting a minimum bus cycle of 1 clock (one for address and one for data phase with limited pipelining). AMBA masters are implemented within the flexible crossbar and a very flexible synchronous protocol converter AMBA-to-IPS gasket (AIPS) is available.
- IPS is a 32-bit single master protocol that needs a minimum of 3 AMBA cycles for unbuffered write and minimum of 2 clocks for periphery read.

Redundancy is implemented for those blocks requiring it to ensure high diagnostic coverage for the key IP (for example: the e200z4 core, the DMA controller, and the AIPS bus bridge with the peripheral subsystems).

The architecture aims to guarantee maximum throughput of 200MHz.

2.3.1 Software debug and calibration

MPC5744P includes many features to facilitate software development. These features include:

- Nexus code execution trace on the main e200z4251n3 core
- Nexus data trace on all bus masters (DMA, Interprocessor bus, CPUs, and others)
- High speed Nexus trace output port consisting of two lanes of Aurora (LVDS) operating up to 1.25 Gbit/s

2.3.2 Compatibility with MPC5643L

The MPC5744P is compatible in important ways with the MPC5643L, a predecessor device in 90 nm CMOS technology. For customers migrating to the MPC5744P, this high degree of compatiblity enables re-use and reduces unnecessary changes. The following table summarizes key aspects of the compatibility.

Table 2-3. MPC5744P Compatibility with MPC5643L

Topic	Remarks for MPC5744P
Package: 144 LQFP	Delivered in the same 144 LQFP with compatible pinout.
Package: 257 MAPBGA	Delivered in the same 257 MAPBGA package. The pinout is compatible, but with limitations due to the new LFAST and Aurora interfaces. Board changes are required.
Power supply concept	Supports an external ballast transistor with internal regulation that allows compatible use. In addition, offers an option with an external supply for the 1.25 V core voltage.
Supply monitoring	The same low voltage monitors for the 1.25 V core voltage and the 3.3 V voltage domains are offered. Both devices offer a high voltage detection for the 1.25 V domain.
Power supply pins	All power supply pins in 144 LQFP package are the same between the two parts, with an exception: the VDD_HV_REG_x pins are replaced with pads for reset/GPIO functionality because the MPC5744P does not offer an internal ballast supply option. When the MPC5744P is soldered into a board designed for the MPC5643L that is unchanged, these GPIOs must not be configured as output.
I/O multiplexing	All I/O multiplexing options in the 144 LQFP package are maintained to allow use of the same peripheral interfaces on the same pins. The MPC5744P adds additional multiplexing for new functionality.
ADC channels and reference voltage	The same pins can be mapped to the same ADC module channels. The ADC are 5 V input capable and have separate reference voltages. The use of ADC pads as inputs on the MPC5744P follows a 5 V I/O specification. In contrast, the specification is 3.3 V on the MPC5643L.
External hardware for safety	The same external components are required as on the MPC5643L: • monitoring of the Error Out interface • external watchdog functionality (periodic communication) • external 3.3 V HVD

2.3.3 Block Diagram

The following figure is a top-level diagram that shows the functional organization of the system.

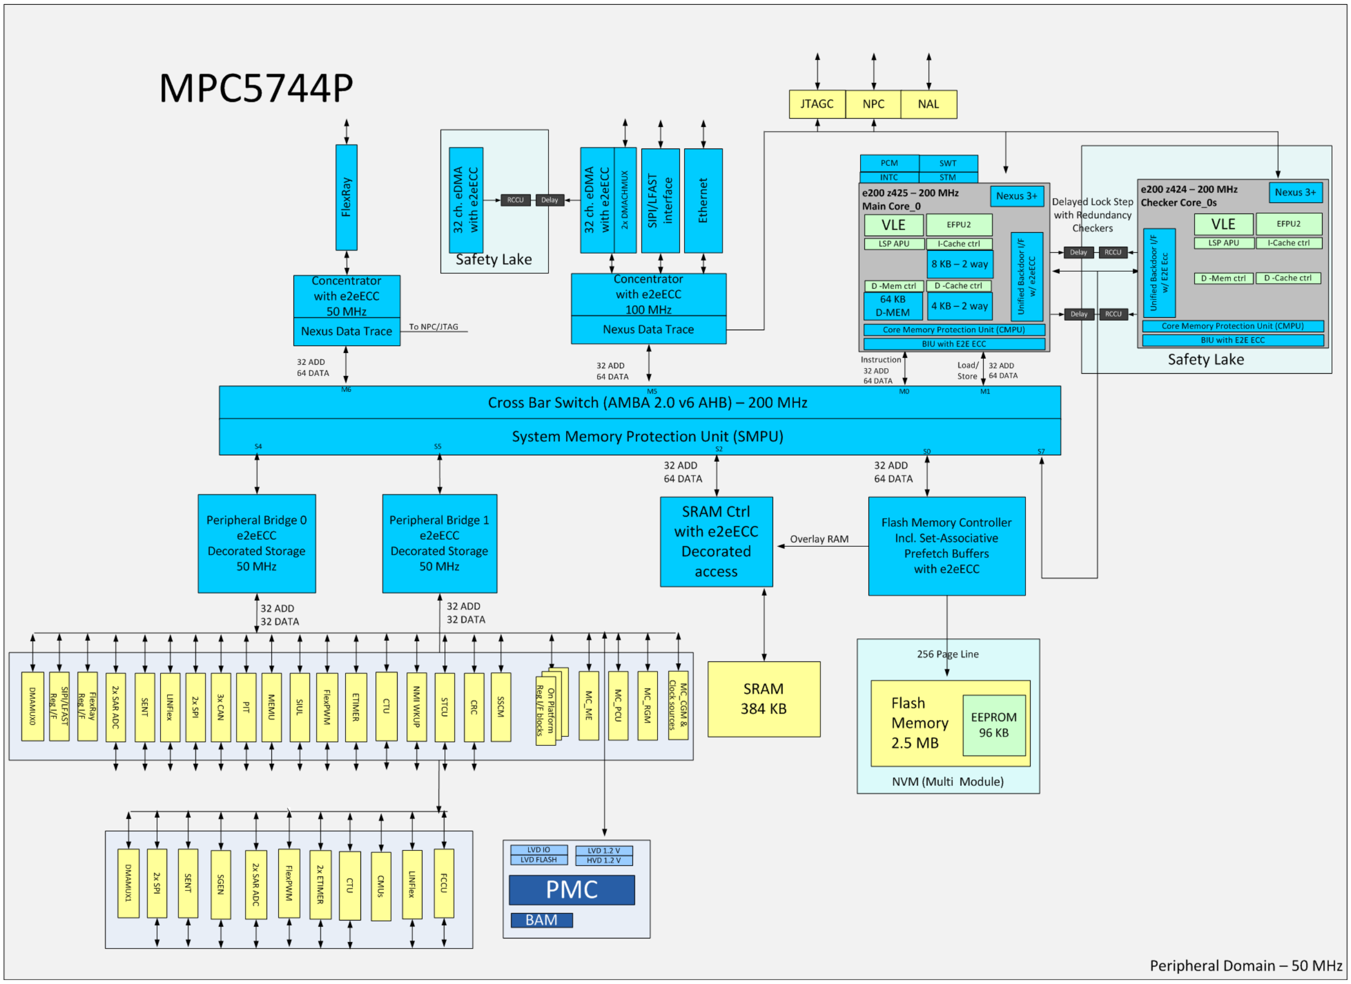

Figure 2-1. System Block Diagram

Chapter 3
Embedded Memories

3.1 Overview

The embedded memory architecture for MPC5744P includes the features:

- Onboard SRAM, including system SRAM, local data memory for each processor core, and overlay SRAM
- Onboard system ECC flash memory
- End-to-end ECC error detection and correction
- Built-in flash memory security features including censorship

3.2 SRAM

3.2.1 System SRAM

MPC5744P includes 384 KB general-purpose on-chip ECC SRAM. The SRAM can be configured for either 0- or 1-wait state read operation latency using the PRCR1 register in the SRAM controller.

- See the SRAM controller memory map and register definition for details on configuration of the SRAM controller.
- See the Memory Map chapter for the MPC5744P SRAM map.

A portion of the system SRAM can be used as the overlay SRAM. *The overlay SRAM* feature included in MPC5744P is part of a comprehensive set of calibration and debug features. Overlay SRAM can be mapped over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables calibration of constant data without requiring additional external RAMs and calibration memory interfaces.

NOTE

Overlay SRAM is normally used for system development purposes only.

Timing for calibration accesses to a particular overlay SRAM are the same as access to the underlying flash if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The overlay function is implemented using registers in the flash memory controller.

1. Using PFLASH Calibration Region Descriptors (PFCRDn) define one or more (up to 32) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

See PFLASH calibration remap support for details on memory overlay (remapping).

3.2.2 Processor core local SRAM

MPC5744P includes local data SRAM (D-MEM) for the processor core to provide enhanced performance.

- Each processor core has 64 KB of data SRAM.

Each area of core SRAM is accessible by other processor cores and bus mastering peripheral devices. See the Memory Map for details.

3.3 Flash memory

Flash memory on MPC5744P consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. The following figure shows the memory architecture.

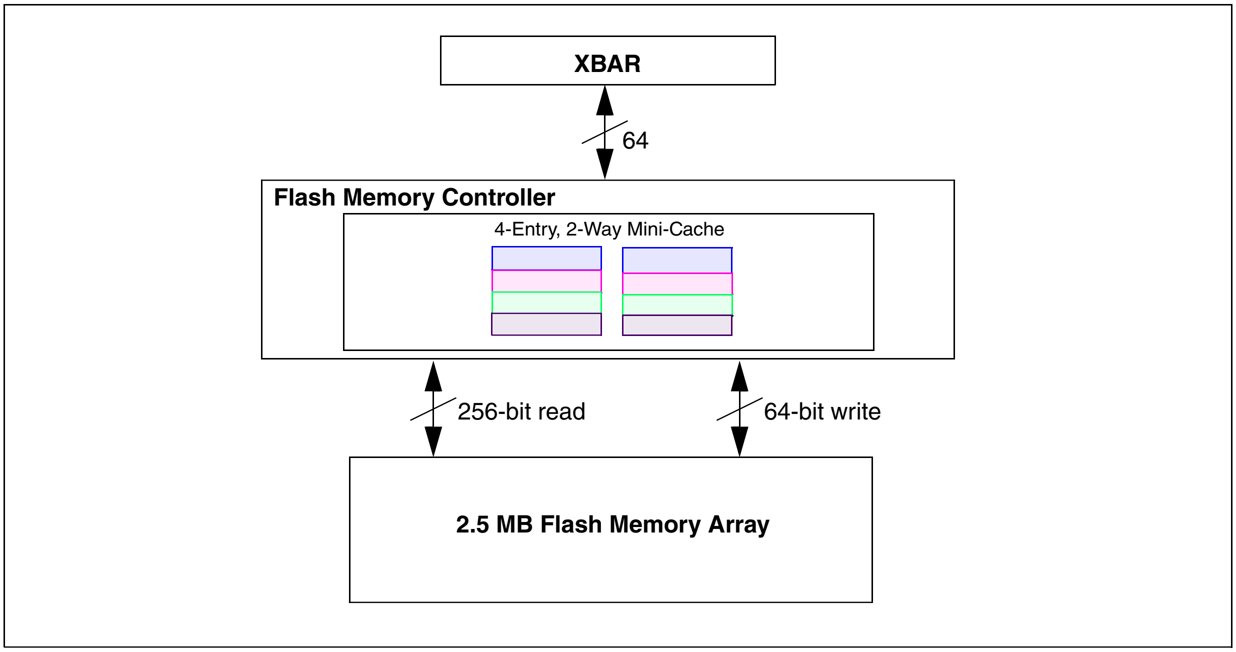

Figure 3-1. Device flash memory block diagram

3.3.1 Flash memory controller

The MPC5744P flash controller acts as an interface between the system bus and the flash array and serves as the interface to the on-chip overlay RAM.

The flash controller contains a 4-entry, 2-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash array access.

The flash memory controller contains configuration registers which manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash.

See the Flash Memory Controller chapter for details.

3.3.2 Flash memory array

The MPC5744P on-chip flash provides programmable, non-volatile flash memory. The non-volatile memory (NVM) can be used for instruction storage, data storage, or both. The flash memory module interfaces the system bus to a dedicated flash memory array controller. It supports a 64-bit data bus width at the system bus port, and a 256-bit read data interface to flash memory. The module contains a 2-way set-associative mini-cache.

3.3.2.1 Features

- 2.5MB of Flash in unique multi partitioned hard macro
- Flash partitioning
  - 4x 16 KB in partition 0/1 (2x blocks EEPROM emulation enabled)
  - 2x 32 KB in partition 2/3 (EEPROM emulation enabled)
  - 6x 64 KB in partition 4/5
  - 8x 256 KB in partition 6/7
- Support for reading-while-writing when the accesses are to different partitions.
- Flash protection
  - Write protection and OTP available for dedicated blocks.
- Test information stored in a non-volatile UTest block which will be OTP.
- Erase suspend, program suspend and erase-suspended program all supported.
- 256 KB address space

3.3.2.2 UTest memory space

MPC5744P contains a 16 KB area of One-Time Programmable (OTP) flash memory for storage of test information and device configuration data. See Chapter 5, Memory Map for the MPC5744P UTEST flash memory map.

3.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC support. This end-to-end ECC (aka e2eECC) is structurally different than traditional "ECC at memory" functionality since it provides for robust error detection capabilities from one endpoint of an information transfer to another endpoint with temporary information storage in an intermediate component(s). While memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors which have occurred on stored data in the memory, e2eECC instead performs generation of error protection codes at the source of data generation, sending the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master, and performs a check of data integrity using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then may regenerate the codes for provision when a request is made to read the stored information, or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated based on more than just the data associated with a storage location in order to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the store data at the data source to generate error protection codes which cover certain types of addressing errors which may occur in the system interconnect or in the memory unit. Checking of the error protection codes may be done at the memory unit on a store to ensure that no corruption of address or data information has occurred while the request has transitioned through the device from the bus master source, as well as to ensure that within the storage memory, address decoding was performed properly (although not all address decoding errors can be detected this way), or it may simply store the received data and protection codes at the address it receives. On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location(s), and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory, or in the retrieved data, thus ensuring that the address sent for the request was not corrupted, that the addressed location was actually accessed (to the extent it is possible to ensure), and that the stored data was error free, to the extend the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust that the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in the following table.

Table 3-1. ECC comparison of data write then read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data + checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave

Table continues on the next page...

Table 3-1. ECC comparison of data write then read sequence (continued)

Traditional ECC	End-to-End ECC (e2eECC)
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations "covered" by the ECC checks is readily apparent. Thus, the e2eECC concept provides improved fault detection capabilities in two important aspects:

1. The entire data transaction, from the initiating bus master, through the entire platform crossbar steering mechanism to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
2. The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error free transfers) in a critical timing arc which often sets the upper limit of operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master, where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic, producing an improved timing arc and generally, higher operating speeds.

Errors which occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requestor. While not all possible errors can be detected this way, this approach provided a substantial improvement versus traditional methods. Additional on-line diagnostics and/or additional hardware should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

Chapter 4
Signal Description

4.1 Production packages

The device has the following production packages:

- 144LQFP
- 257MAPBGA

The following table shows features/pins provided by the 257MAPBGA compared to the 144LQFP.

Table 4-1. MPC5744P features differing by package

Feature	144LQFP	257MAPBGA
FlexPWM1	A[0-2]/B[0-2]	A[0-3]/B[0-3]/X[0-3]/Fault[0:3]
eTimer2	ETC2-5	ETC0-5
Supplies	3.3V (IO): 4xV_{DD}, 4xV_{SS} 3.3V (PMU): 1xV_{DD} 3.3V (OSC): 1xV_{DD}[1] 3.3V (flash): 1xV_{DD}[1] 1.25V (core): 6xV_{DD}, 8xV_{SS} 1.25V (PLL): 1xV_{DD},[1] 1xV_{SS} 1.25V (flash): 1xV_{DD}[1, 2] 3.3V/5V (ADR): 2xV_{DD}, 2xV_{SS} 3.3V (ADV): 1xV_{DD}, 1xV_{SS}	Additional supplies beyond 144LQFP: 3.3V (IO): 5xV_{DD}, 15xV_{SS} 1.25V (LFAST): 1xV_{DD} 1.25V (core): 18xV_{DD}, 17xV_{SS}
GPIO	79 GPIO 26 GPI	Additional GPIO beyond 144LQFP: 33 GPIO 3 GPI 2 LFAST differential pads Aurora Interface: 2x transmit, 1x receive (reference clock)
DSPI3	No external signals	CS0-3

Table continues on the next page...

Table 4-1. MPC5744P features differing by package (continued)

Feature	144LQFP	257MAPBGA
CTU external trigger(s)	CTU0	CTU0 CTU1
ADCs[3]	• 22 analog pads assigned to ADC0, ADC1, ADC2, and ADC3 • Shared channels between ADC0/ADC1, ADC0/ADC2, and ADC1/ADC3	• 25 analog pads assigned to ADC0, ADC1, ADC2, and ADC3 • Shared channels between ADC0/ADC1, ADC0/ADC2, ADC1/ADC3, and ADC2/ADC3
SIPI/ LFAST interface	No	Yes
Ethernet	No	Yes
Nexus	Yes (MDO interface)	Yes (MDO interface)
Nexus Aurora port	No	Yes (TX0/TX0_P/TX1/TX1_P/CLK/CLK_P)

1. V_{SS} connected to Core Ground on 144LQFP
2. 1.25V flash memory supply connected to Core Supply on 144LQFP (93)
3. For all packages, internal analog sources/supplies can be connected to ADC0, ADC1, ADC2, and ADC3.

Case numbers for outline drawings of each package are provided in the MPC5744P Data Sheet.

4.2 Package pinouts and ballmap

The following figures show the LQFP pinout and the BGA ballmap.

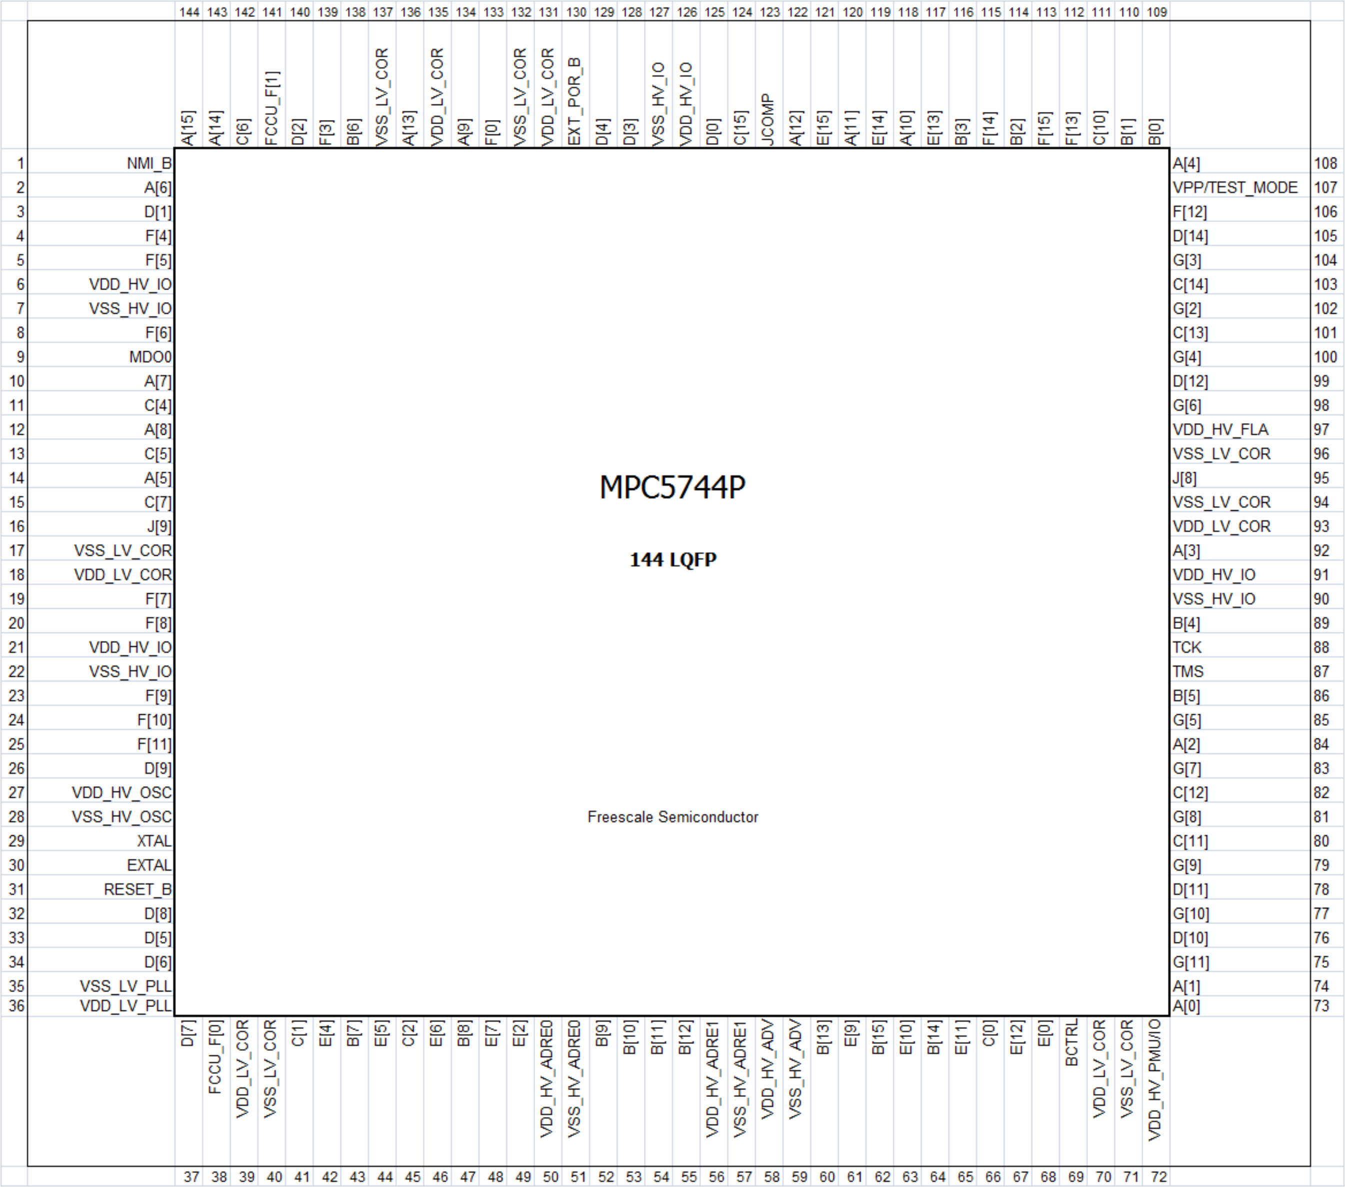

Figure 4-1. 144LQFP pinout

Figure 4-2. 257MAPBGA ballmap

4.3 Pin/ball descriptions

The following sections provide signal descriptions and related information about the functionality and configuration of the device. Note that this section is under development.

4.3.1 Pin/ball startup and reset states

The following table provides startup state and reset state information for device pins/balls.

The startup state and subsequent states of the following pins/balls cannot be configured by the user:

- JCOMP
- TMS
- TCK
- XTAL/EXTAL
- FCCU_F[0] and FCCU_F[1]
- EXT_POR_B
- RESET_B

The user can configure the state after reset of the following pins/balls by programming the applicable MSCRs/IMCRs:

- GPIOs
- Analog inputs
- TDI
- TDO
- NMI_B
- FAB
- ABS[0]
- ABS[2]

Table 4-2. Pin/ball startup and reset states

Pin/ball	Startup state[1]	State during reset	State after reset	144LQFP	257MAPBGA
GPIOs	hi-z	hi-z	hi-z	Note	Note[2]
Analog inputs[3]	hi-z	hi-z	hi-z	Note[2]	Note[2]
JCOMP (TRST)	hi-z	input, weak pull-down	input, weak pull-down	Note	Note[4]
TDI	hi-z	input, weak pull-up	input, weak pull-up	Note[4]	Note[4]
TDO	hi-z	output, hi-z	output, hi-z	Note[4]	Note[4]
TMS	hi-z	input, weak pull-up	input, weak pull-up	Note[4]	Note[4]

Table continues on the next page...

Table 4-2. Pin/ball startup and reset states (continued)

Pin/ball	Startup state[1]	State during reset	State after reset	144LQFP	257MAPBGA
TCK[5]	hi-z	input, weak pull-up	input, weak pull-up	Note[4]	Note[4]
XTAL/EXTAL	hi-z	hi-z	hi-z	Note[4]	Note[4]
FCCU_F[0][5]	hi-z	input, hi-z	output/input, hi-z	38	R2
FCCU_F[1][5]	hi-z	input, hi-z	output/input, hi-z	141	C4
EXT_POR_B	hi-z	input, weak pull-down	input, weak pull-down	Note[4]	Note[4]
RESET_B	hi-z	input, weak pull-down	input, weak pull-down	Note[4]	Note[4]
NMI_B	hi-z	input, weak pull-up	input,weak pull-up	Note[4]	Note[4]
FAB	hi-z	input, weak pull-down	input, weak pull-down	Note[4]	Note[4]
ABS[2]	hi-z	input, weak pull-down	input, weak pull-down	Note[4]	Note[4]
ABS[0]	hi-z	input, weak pull-down	input, weak pull-down	Note[4]	Note[4]

1. Startup state is exited when the core and high-voltage supplies reach minimum levels as defined in the Power Management chapter.
2. See Generic pins/balls.
3. Not all non-supply or reference pins on the device are explicitly defined in this table.
4. See System pins/balls.
5. This pin/ball is dedicated to and directly connected to a peripheral module pin.

4.3.3 System pins/balls

The following table contains information about system pin functions for the devices.

Table 4-4. System pins/balls

Symbol	Type	Description	144LQFP	257MAPBGA
NMI_B	Input	Non-maskable Interrupt	1	E4
XTAL	Input	Crystal Oscillator/External Clock Input	29	N1
EXTAL	Input	Input of the oscillator amplifier circuit	30	R1
RESET_B	Input	Functional Reset	31	P2
EXT_POR_B	Input	External Power On Reset	130	D6
VPP_TEST[1]	Input	SoC Test Mode	107	D15
JCOMP	Input	JTAGC, JTAG Compliance Enable	123	A6
TCK	Input	JTAGC, Test Clock Input	88	H17
TMS	Input	JTAGC, Test Mode Select	87	H15
TDO	Output	JTAGC, Test Data Out	89	G14

Table continues on the next page...

Table 4-4. System pins/balls (continued)

Symbol	Type	Description	144LQFP	257MAPBGA
TDI	Input	JTAGC, Test Data Input	86	J17
MDO[0]	Output	NEXUS, Message data out pins; reflects the state of the internal power on reset signal until RESET is negated	9	G1
MDO[3:1]	Output	NEXUS, Message data out pins	4,5,8	E1, F1, E2
EVTO	Output	NEXUS, Event Out Pin	24	K2
EVTI	Input	NEXUS, Event In Pin	25	L2
MCKO	Output	NEXUS, Message clock out pin	19	J4
MSEO[1:0]	Output	NEXUS, Message Start/End out pin	20, 23	J3, K3
RDY_B	Output	NEXUS, Read/Write Transfer completed	—	J2
			16	K1
BCTRL	Output	Base control signal of external npn ballast	69	R13
J[11], J[10]	--	FSL Factory Test[2]	—	L17, K17

1. VPP_TEST must be connected to ground.
2. Do not connect on the board.

4.3.4 LVDS pins/balls

The following tables contain information on LVDS pin functions for the devices.

Table 4-5. SIPI LFAST LVDS pin descriptions

Functional block	Port pin	Signal	Signal description	Direction	257MAPBGA
SIPI LFAST[1, 2]	I[5]	SIPI_TXN	Interprocessor Bus LFAST, LVDS Transmit Negative Terminal	O	N15
	C[12]	SIPI_TXP	Interprocessor Bus LFAST, LVDS Transmit Positive Terminal	O	M14
	I[6]	SIPI_RXN	Interprocessor Bus LFAST, LVDS Receive Negative Terminal	I	M15
	G[7][3]	SIPI_RXP	Interprocessor Bus LFAST, LVDS Receive Positive Terminal	I	M16

1. DRCLK and TCK/DRCLK usage for SIPI LFAST are described in the reference manual's SIPI LFAST chapters.
2. For the MSCR SSS value of the port pin, see Table 1.
3. The 144LQFP package has G[7] and C[12] but no SIPI LFAST functionality.

CAUTION

SIPI LFAST pins are muxed with GPIOs. Do not use GPIO and SIPI LFAST functionality in parallel.

Table 4-6. Aurora LVDS pin descriptions

Functional block	Pad	Signal	Signal description	Direction	257MAPBGA[1]
Nexus Aurora High Speed Trace	G[12]	TX0P	Nexus Aurora High Speed Trace Lane 0, LVDS Positive Terminal	O	H14
	G[13]	TX0N	Nexus Aurora High Speed Trace Lane 0, LVDS Negative Terminal	O	J14
	G[14]	TX1P	Nexus Aurora High Speed Trace Lane 1, LVDS Positive Terminal	O	L15
	G[15]	TX1N	Nexus Aurora High Speed Trace Lane 1, LVDS Negative Terminal	O	K14
	H[0]	CLKP	Nexus Aurora High Speed Trace Clock, LVDS Positive Terminal	I	K15
	H[1]	CLKN	Nexus Aurora High Speed Trace Clock, LVDS Negative Terminal	I	J15

1. Nexus Aurora High Speed Trace is available only on the 257MAPBGA.

4.3.5 Generic pins/balls

The I/O signal descriptions for the device are in the following table. It contains the port definition, multiplexing, direction, pad type, and package pin/ball numbers for each I/O pin on the device.

MSCR registers are used for alternative (ALT) mode selection and programming of pad control options.

IMCR registers are used to configure input muxing by peripheral. See Peripheral input muxing for details.

See Table 4-16 for the MSCR register address map and Table 4-17 for the IMCR register address map.

Table 4-7. Pin muxing

NMI_B	MSCR[154]	0000 (Default)	NMI_B	Core	Non-Maskable Interrupt	I	1	E4

1. Selecting an alternative function with a "Reserved" source function causes the pin to enter a null state (input buffer and output buffer enables are both 0).
2. **(Default) = ALT mode configuration after reset.**
3. Changing the B[5] configuration during debug might affect the availability of TDI.
4. ADC analog input: Program corresponding MSCR APC bit and enable ADC to switch on the analog input path. See Table 1 for details.
5. Shared with SIPI LFAST transmit pad SIPI_TXP. Alternative modes and GPIO must be disabled (OBE=0, IBE=0) if port is used for SIPI LFAST.
6. To operate D[7] as GPIO, disable the Sine Wave Generator (SGEN) and the peripheral bus clock of the SGEN: Program the MC_ME_PCTL239 register to select an MC_ME_RUN_PCn (or MC_ME_LP_PCn) configuration where the field for the desired mode is 0.
7. SGEN output if SGEN is enabled. See Table 1 for details.
8. Shared with SIPI LFAST receive pad SIPI_RXP. Alternative modes and GPIO must be disabled (OBE=0, IBE=0) if port is used for SIPI LFAST.
9. Shared with SIPI LFAST receive pad SIPI_TXN. Alternative modes and GPIO must be disabled (OBE=0, IBE=0) if port is used for SIPI LFAST.
10. Shared with SIPI LFAST receive pad SIPI_RXN. Alternative modes and GPIO must be disabled (OBE=0, IBE=0) if port is used for SIPI LFAST.

The following table list ports that are not implemented. The corresponding control and data registers are not implemented.

Table 4-8. Ports - Not Implemented

Port Name	Port Index
C	3,8,9
D	13,15
E	1,3,8
F	1,2
G	0,1,[12:15]
H	[0:3]
J	[10:15]

Any attempt to access unimplemented MSCRs generates a bus error. The read value from unimplemented ports must be masked in case of parallel port accesses.

4.3.6 Peripheral input muxing

The following table describes the peripheral muxing capabilities of the device. See Table 4-17 for IMCR register addresses.

Table 4-9. Peripheral muxing

Destination peripheral	Destination functions	IMCR number	IMCR[SSS] field value	Source peripherals	Source functions
FlexCAN_0	RXD	IMCR[32]	0000 (Default)[1]	—	Disable
			0001	I/O-Pad	A[15]
			0010	I/O-Pad	B[1]
			0011-1111	—	Reserved[2]

ENET_0	CRS	IMCR[231]	0000 (Default)	—	Disable
			0001	I/O-Pad	H[4]
			0010-1111	—	Reserved
ENET_0	RX_ER	IMCR[232]	0000 (Default)	—	Disable
			0001	I/O-Pad	I[1]
			0010-1111	—	Reserved
ENET_0	TX_CLK	IMCR[233]	0000 (Default)	—	Disable
			0001	I/O-Pad	G[8]
			0010-1111	—	Reserved

1. (Default) = configuration after reset
2. Selecting an alternate function with a 'Reserved' source function causes the pin to enter a null state (Input buffer and Output buffer enables both at 0).

Table 4-10. Peripheral muxing example

SSS field value in IMCR[214]	Result
0001	I/O-Pad I[12] is connected to SENT_1 Receive input SENT_RX[1]
0010	I/O-Pad J[6] is connected to SENT_1 Receive input SENT_RX[1]

See Table 4-8 concerning the availability of port pins on the packages.

4.3.7 Pins with analog functions

The following table describes pins with analog functions.

Table 4-11. Pins with analog functions

Pin	144LQFP	257MAPBGA	Connected Analog IPs	Analog Function[1]	MSCR#
B[7]	43	R5	ADC0	AN[0]	23
B[8]	47	P7	ADC0	AN[1]	24
B[9]	52	U7	ADC0/ADC1	AN[11]	25
B[10]	53	R8	ADC0/ADC1	AN[12]	26
B[11]	54	T8	ADC0/ADC1	AN[13]	27
B[12]	55	U8	ADC0/ADC1	AN[14]	28
B[13]	60	R10	ADC1	AN[0]	29
B[14]	64	P11	ADC1	AN[1]	30
B[15]	62	R11	ADC1	AN[2]	31
C[0]	66	R12	ADC1	AN[3]	32
C[1]	41	T4	ADC0	AN[2]	33
C[2]	45	U5	ADC0	AN[3]	34
D[7]	37	R4	Sine Wave Generator Out	anaout	NA[2]
E[0]	68	T13	ADC1	AN[5]	64
			ADC3	AN[4]	
E[2]	49	U6	ADC0	AN[5]	66
E[4]	42	U4	ADC0	AN[7]	68
E[5]	44	T5	ADC0	AN[8]	69
E[6]	46	R6	ADC0/ADC2	AN[4]	70
E[7]	48	T6	ADC0	AN[6]	71
E[9]	61	U10	ADC1	AN[7]	73
			ADC3	AN[6]	
E[10]	63	T11	ADC1	AN[8]	74
			ADC3	AN[7]	
E[11]	65	U11	ADC1	AN[4]	75
			ADC3	AN[3]	
E[12]	67	T12	ADC1	AN[6]	76
			ADC3	AN[5]	
J[5]		P8	ADC2/ADC3	AN[0]	149
J[6]		P9	ADC2/ADC3	AN[1]	150
J[7]		P10	ADC2/ADC3	AN[2]	151

[1] For pin multiplexed ADC functions - both ADCs will have the same channel number unless otherwise specified.

[2] The Sine Wave Generator must be enabled to switch on the analog output function.

4.3.8 Mapping of ports to PGPDO registers

The following table shows the mapping of the GPIO ports to the Parallel GPIO Pad Data Out (PGPDO) registers. See the dedicated SIUL2 chapter for more information.

Table 4-12. Mapping of ports to PGPDO registers

Port[1]	Port width	PGPDO field[2]	Address
A	16	PPDO[0]	0xFFFC1700
B	16	PPDO[1]	0xFFFC1702
C	16	PPDO[2]	0xFFFC1704
D	16	PPDO[3]	0xFFFC1706
E	16	PPDO[4]	0xFFFC1708
F	16	PPDO[5]	0xFFFC170A
G	16	PPDO[6]	0xFFFC170C
H	16	PPDO[7]	0xFFFC170E
I	16	PPDO[8]	0xFFFC1710
J	16	PPDO[9]	0xFFFC1712

[1] See Ports - Not Implemented table for unimplemented port pins.
[2] All fields are 16 bits wide.

The following table shows the mapping of the GPIO ports to Parallel GPIO Pad Data In (PGPDI) registers. See the dedicated SIUL2 chapter for more information

Table 4-13. Mapping of ports to PGPDI registers

Port[1]	Port width	PGPDI field[2]	Address
A	16	PPDI[0]	0xFFFC1740
B	16	PPDI[1]	0xFFFC1742
C	16	PPDI[2]	0xFFFC1744
D	16	PPDI[3]	0xFFFC1746
E	16	PPDI[4]	0xFFFC1748
F	16	PPDI[5]	0xFFFC174A
G	16	PPDI[6]	0xFFFC174C
H	16	PPDI[7]	0xFFFC174E
I	16	PPDI[8]	0xFFFC1750
J	16	PPDI[9]	0xFFFC1752

[1] See Ports - Not Implemented table for unimplemented port pins.
[2] All fields are 16 bits wide.

4.3.9 Address map and configuration for MSCR/IMCR registers

The following tables provide the memory map for the MSCRs and IMCRs used to configure alternative modes and peripheral input muxing. See the SIUL2 chapter for the registers' layouts.

Table 4-16 shows the default settings for the pad control fields and which pad control fields are programmable (see Table 4-15 for conventions).

The default settings (configuration after reset) for the MSCR SSS fields are documented in Table 4-7.

Table 4-17 shows the IMCRs by peripheral: destination function, IMCR number, IMCR address, default configuration and programmability of the INV field, and default value for the SSS field.

Table 4-14. MSCR pad control fields

MSCR field	Brief description
SRC[1:0]	Slew Rate Control
OBE	Output Buffer Enable
ODE	Open Drain Enable
SMC	Safe Mode Control
APC	Analog Pad Control
IBE	Input Buffer Enable
HYS	Input Hysteresis
PUS	Pull Select: 0 = Pulldown, 1 = Pullup
PUE	Pull Enable: 0 = Disabled, 1 = Enabled
INV	Invert

Table 4-15 describes conventions used in Table 4-16 and Table 4-17.

Table 4-15. Conventions used in following MSCR and IMCR tables

Abbreviation	Configuration during/after reset	Programmable by user?
D	Disabled	No: permanently disabled or not implemented
E	Enabled	No: permanently enabled
P(0)	Reset value is 0	Yes
P(1)	Reset value is 1	Yes
P(D)	Disabled	Yes
P(E)	Enabled	Yes
P(PD)	Pulldown	Yes
P(PU)	Pullup	Yes
PD	Pulldown	No: permanently selected
PU	Pullup	No: permanently selected

Table 4-16. MSCR addresses and default settings

Data Pin	MSCR #	Hex address	SRC[1]	SRC[0][1]	OBE	ODE	SMC	APC	IBE	HYS	PUS	PUE	INV

[1] P(D) means the Invert function is disabled by default but can be programmed by the user.

Chapter 5
Memory Map

5.1 Memory Map

The following table shows the device memory map for the MPC5744P.

All addresses on the MPC5744P, including many that are reserved, are identified in the table. The addresses represent the physical addresses assigned to each region or module name. All memory not listed in this table is reserved, and access to those locations may produce undesirable results.

Table 5-1. Overview memory map

Start address	End address	Allocated size	Used size	PCTL number	Description
Flash memory—see Table 5-4 for details					
0x00000000	0x003FFFFF	-			Reserved
0x00400000	0x00403FFF	16 KB		-	UTest NVM block - no overlay See Table 5-6 for details
0x00404000	0x007FFFFF	-			Reserved
0x00800000	0x00817FFF	96 KB		-	Data flash memory blocks - no overlay
0x00818000	0x009FFFFF	-			Reserved
0x00A00000	0x00FFFFFF	6 MB	416 KB	-	Small and medium flash memory blocks - no overlay
0x01000000	0x01FFFFFF	16 MB	2048 KB	-	Large flash memory blocks - no overlay
0x02000000	0x089FFFFF	106 MB			Reserved
0x08A00000	0x08FFFFFF	6 MB	416 KB	-	Mirror small and medium flash memory blocks - no overlay

Table continues on the next page...

Table 5-1. Overview memory map (continued)

Start address	End address	Allocated size	Used size	PCTL number	Description
0x09000000	0x09FFFFFF	16 MB	2048 KB	-	Mirror large flash memory blocks - no overlay
0x0A000000	0x3FFFFFFF	-			Reserved

Table 5-1. Overview memory map (continued)

Start address	End address	Allocated size	Used size	PCTL number	Description
0xFFFE0000	0xFFFE3FFF	16 KB		-	Flash main control registers
0xFFFE4000	0xFFFF7FFF	-			Reserved
0xFFFF8000	0xFFFFBFFF	16 KB		-	System Status and Configuration Module (SSCM)
0xFFFFC000	0xFFFFFFFF	16 KB		-	Boot Assist Module (BAM)

1. DMA is a platform IP and in low power modes the clock to all platform IPs is shut off. Therefore the DMA cannot be kept ON in low power modes. So PCTL has no impact during STOP/HALT. modes.
2. The PMC register locations overlap with the memory map slot of the MC_PCU. For more information, see Power control registers.
3. The locations of the IRCOSC, XOSC, and PLLDIG modules' registers overlap with the memory map slot of the MC_CGM. For more information, see Clock generation registers.

5.1.1 Power control registers

The MC_PCU works as a bus bridge for the PMC module. The locations of the PMC's registers overlap with the memory map slot allocated to the MC_PCU. The following table identifies the offsets of the MC_PCU and PMC registers relative to the base address of the MC_PCU.

Table 5-2. MC_PCU memory slot and relative register locations

Start offset (hex)	End offset (hex)	Module registers
0000	0043	MC_PCU registers
0044	03FF	Reserved
0400	07FF	PMC registers
0800	3FFF	Reserved

5.1.2 Clock generation registers

The MC_CGM works as a bus bridge for the IRCOSC, XOSC, and PLLDIG modules. The locations of these modules' registers overlap with the memory map slot allocated to the MC_CGM. The following table identifies the offsets of these registers, including the actual MC_CGM registers, relative to the base address of the MC_CGM.

Table 5-3. MC_CGM memory slot and relative module register locations

Start offset (hex)	End offset (hex)	Module registers
0000	003F	IRCOSC registers
0040	007F	Reserved
0080	00BF	XOSC registers
00C0	00FF	Reserved
0100	013F	PLLDIG registers
0140	06FF	Reserved
0700	08CB	MC_CGM registers
08CC	3FFF	Reserved

5.1.3 Flash memory and RAM memory maps

The following table is the detailed flash memory map for the MPC5744P.

Table 5-4. Flash memory map

Start address	End address	Allocated size (KB)	Complete flash memory block structure	RWW partition	Block size
Reserved - no overlay					
0x00000000	0x003FFFFF	-	Reserved		
UTest NVM block - no overlay

Chapter 6
Functional Safety

6.1 Introduction

The MPC5744P is developed according to ISO 26262 and has an integrated safety concept targeting safety-related systems requiring high safety integrity levels. In order to support the integration of the MPC5744P into safety-related systems, the following documentation is available:

- Reference Manual (MPC5744PRM) - Describes the MPC5744P functionality
- Data Sheet (MPC5744PDS) - Describes the MPC5744P operating conditions
- Safety Manual (MPC5744PSM) - Describes the MPC5744P safety concept and possible safety mechanisms (integrated in MPC5744P, system level hardware or system level software), as well as measures to reduce dependent failures
- Dynamic FMEDA - Inductive analysis enabling customization of system level safety mechanisms, including the resulting safety metrics for ISO 26262 (SPFM, LFM & PMHF) and IEC 61508 (SFF & Beta IC Factor)
- FMEDA Report - Describes the FMEDA methodology and safety mechanisms supported in the FMEDA, including source of failure rates, failure modes and assumptions made during the analysis.

The Reference Manual, Data Sheet and Safety Manual are available for download on the MPC5744P product page. The Dynamic FMEDA and FMEDA report are available upon request. The MPC5744P is a SafeAssure solution; for further information regarding functional safety at Freescale, visit www.freescale.com/safeassure.

Chapter 7
Chip Configuration

7.1 Introduction

This information consists of details about the individual modules of the microcontroller. The information includes:

- module block diagrams showing immediate connections within the device,
- specific module-to-module interactions not necessarily discussed in the individual module chapters, and
- links for more information.

7.2 Core modules

The microcontroller has two separate cores that perform various computational and control functions.

- The Main Core_0 uses an e200z425n3 core. This core is used for general computational functions.
- The Checker Core_0s uses an e200z424 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to insure that Main Core_0 is executing correctly.

For more information, see the Core Complex Overview.

7.2.1 Core reset settings

The following table shows the state of the *PowerISA 2.06* architected registers and other optional resources immediately after a system reset.

Table 7-1. Reset settings for e200z4 resources

1. The levels that determine these bits are set by the factory and may change between revisions of the device.
2. Undefined on **POR** assertion, unchanged on **external PORESET (EXT_POR_B)** assertion.
3. Reset by processor reset **external PORESET (EXT_POR_B)** if DBCR0[EDM]=0, as well as unconditionally by **POR**.
4. Read-only registers.

7.2.2 Special Purpose Register summary

PowerISA 2.06 and implementation-specific SPRs for the e200z4251n3 and e200z424 cores are listed in the following table. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR may be read or written with the **mfspr** and **mtspr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in the following table.

Table 7-2. Special Purpose Registers

Mnemonic	Name	SPR number	Access	Privileged	e200z specific
XER	Integer Exception Register	1	R/W	No	No
LR	Link Register	8	R/W	No	No
CTR	Count Register	9	R/W	No	No
SRR0	Save/Restore Register 0	26	R/W	Yes	No
SRR1	Save/Restore Register 1	27	R/W	Yes	No
PID0	Process ID Register	48	R/W	Yes	No
CSRR0	Critical Save/Restore Register 0	58	R/W	Yes	No
CSRR1	Critical Save/Restore Register 1	59	R/W	Yes	No
DEAR	Data Exception Address Register	61	R/W	Yes	No
ESR	Exception Syndrome Register	62	R/W	Yes	No
IVPR	Interrupt Vector Prefix Register	63	R/W	Yes	No
USPRG0 (VRSAVE)	User SPR General 0 (renamed to VRSAVE in PowerISA 2.06)	256	R/W	No	No
SPRG0	SPR General 0	272	R/W	Yes	No
SPRG1	SPR General 1	273	R/W	Yes	No
SPRG2	SPR General 2	274	R/W	Yes	No
SPRG3	SPR General 3	275	R/W	Yes	No
PIR	Processor ID Register	286	R/W	Yes	No

L1CSR0	L1 cache control and status register 0	1010	R/W	Yes	Yes
L1CSR1	L1 cache control and status register 1	1011	R/W	Yes	Yes
BUCSR	Branch Unit Control and Status Register	1013	R/W	Yes	Yes

Table continues on the next page...

Table 7-2. Special Purpose Registers (continued)

Mnemonic	Name	SPR number	Access	Privileged	e200z specific
MPU0CSR0	MPU0 configuration register	1014	R/W	Yes	Yes
MMUCFG	MMU/MPU configuration register	1015	Read-only	Yes	Yes
L1FINV0	L1 cache flush and invalidate control register 0	1016	R/W	Yes	Yes
SVR	System Version Register	1023	Read-only	Yes	Yes

1. The Debug Status Register can be read using *mfspr RT,DBSR*. The Debug Status Register cannot be written to directly. Instead, bits in the Debug Status Register corresponding to ‘1’ bits in GPR(RS) can be cleared using *mtspr DBSR,RS*.
2. Undefined on **POR** assertion, unchanged on **external PORESET (EXT_POR_B)** assertion.
3. The Machine Check Syndrome Register can be read using *mfspr RT,MCSR*. The Machine Check Syndrome Register cannot be written to directly. Instead, bits in the Machine Check Syndrome Register corresponding to ‘1’ bits in GPR(RS) can be cleared using *mtspr MCSR,RS*.
4. The 64-bit DVC registers are accessed by using the DVC1 and DVC2 SPR numbers for the lower 32 bits and the DVC1U and DVC2U SPR numbers for the upper 32 bits.

7.2.3 Core reservation instructions

This device’s core platform does not use reservation functionality. The core executes reservation instructions, but these instructions do not block other bus masters.

7.3 Platform Configuration Module (PCM)

The Platform Configuration Module contains miscellaneous configuration registers for the device. Currently, the configuration registers are related to the operation of the intelligent bus bridging gasket. The module is mapped to AIPS on-platform slot 10 with a base address of 0xFC02_8000.

PCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4	Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)	32	R/W	0007_0707h	7.3.1/179
8	Bus Bridge Configuration Register 2 (PCM_IAHB_BE2)	32	R/W	0007_0707h	7.3.2/180
C	Bus Bridge Configuration Register 3 (PCM_IAHB_BE3)	32	R/W	0000_0707h	7.3.3/181

7.3.1 Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)

This register, which must be accessed in supervisor mode, configures the bus bridge gasket for the DMA/SIPI/Ethernet port concentrator.

Address: 0h base + 4h offset = 4h

31 BWE_A	Burst Write Enable Controls the bus gasket's handling of burst write transactions for PBRIDGE_0. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.

7.4 System modules

7.4.1 System Integration Unit Lite2 (SIUL2) configuration

The SIUL2 controls MCU reset configuration, pad configuration, external interrupt, general purpose I/O (GPIO), internal peripheral multiplexing, and the system reset operation. The reset configuration block contains the external pin boot configuration logic. The pad configuration block controls the static electrical characteristics of I/O pins. The GPIO block provides uniform and discrete input/output control of the I/O pins of the MCU.

The SIUL2 provides the following features:

- Centralized pad control on per pin basis
- Pin function selection
- Configurable weak pull-up/down
- Configurable slew rate control
- Hysteresis on GPIO pins
- Configurable automatic safe mode pad control
- Input filtering for external interrupts with digital glitch filters

7.4.1.1 SIUL2 interrupts

The SIUL2 supports 32 external interrupts on this device.

The 32 external interrupt sources are grouped into 4 sets with 8 sources each. Each of the 4 groups is assigned one interrupt vector and mapped to the INTC. Each external interrupt source can be masked, and its status can be read individually. Glitch filters are implemented for each external interrupt source.

7.4.1.2 Reset values of MIDRn

The following table provides these registers' reset values.

Table 7-3. MIDRn reset values

Register		144LQFP	257MAPBGA
MIDR1[1]	1N15P	5744_3413h	5744_4013h[2]
	1N65H	5744_3412h	5744_4012h
MIDR2		3900_5000h for MPC5744 3800_5000h for MPC5743 3200_5000h for MPC5742 3000_5000h for MPC5741	3900_5000h for MPC5744 3800_5000h for MPC5743 3200_5000h for MPC5742 3000_5000h for MPC5741

1. The 5744h portion of the reset value applies for MPC5744P, MPC5743P, MPC5742P, and MPC5741P.
2. The reset value of the PKG field corresponds to a 208MAPBGA package because the 257MAPBGA package has 208 balls in its outer sections. The 257MAPBGA package has an additional 49 power and ground balls in an inner section.

7.4.2 Crossbar Switch Integrity Checker (XBIC) configuration

XBIC_0 on this device supports the master and slave ports shown in Table 7-4.

Table 7-4. XBIC_0 master and slave ports supported on this chip

Port type	Available port numbers
Master	0, 1, 5, 6
Slave	0, 2, 4, 5, 7

As a result, for XBIC_0, the available fields in the MCR and ESR are as shown in Table 7-5. The other fields are unused.

Table 7-5. XBIC_0 MCR and ESR field availability on this chip

Register	Available fields
MCR	ME0 ME1 ME5 ME6 SE0 SE2 SE4 SE5 SE7
ESR	DPME0 DPME1 DPME5 DPME6 DPSE0 DPSE2 DPSE4 DPSE5 DPSE7 MST SLV SYN VLD

XBIC_1 supports the three masters connected to the 3-to-1 port concentrator.

Table 7-6. XBIC_1 connections

XBIC_1 port	Connects to
Master 2 (M2)	ENET
Master 1 (M1)	SIPI
Master 0 (M0)	DMA_0
Slave 0 (S0)	AXBS module's M5 port

As a result, for XBIC_1, the available fields in the MCR and ESR are as shown in Table 7-7. The other fields are unused.

Table 7-7. XBIC_1 MCR and ESR field availability on this chip

Register	Available fields
MCR	ME0 ME1 ME2 SE0
ESR	DPME0 DPME1 DPME2 DPSE0 MST SLV SYN VLD

7.4.3 Crossbar Switch (XBAR) configuration

The multi-port Crossbar Switch concurrently supports up to 4 simultaneous connections between master ports and slave ports. It supports the AMBA AHB2.0 AHB-Lite protocol with AMBA V6 extensions for exclusive access support, extended cache control attributes, and misaligned data transfers (referred to as AHB2v6). The Crossbar Switch supports a 32-bit address bus width and a 32 or 64-bit data bus width at all master and slave ports. It also supports both address and data sideband signals which are used to implement decorated storage and the e2eECC for the MPC5744P. A flow-through design allows zero wait-state slave responses.

The Crossbar Switch provides the following features:

- Four master ports and five slave ports (see the following figure)

- 32-bit Address, 64-bit Data paths (applies to all ports) with misaligned access signaling
- Concurrent transfers between independent master and slave ports
- Programmable arbitration priorities on a per-slave port basis
- Round-robin arbitration available on a per-slave port basis
- Parking on slave ports: explicit master, park_on_last_master, none (low power parking)

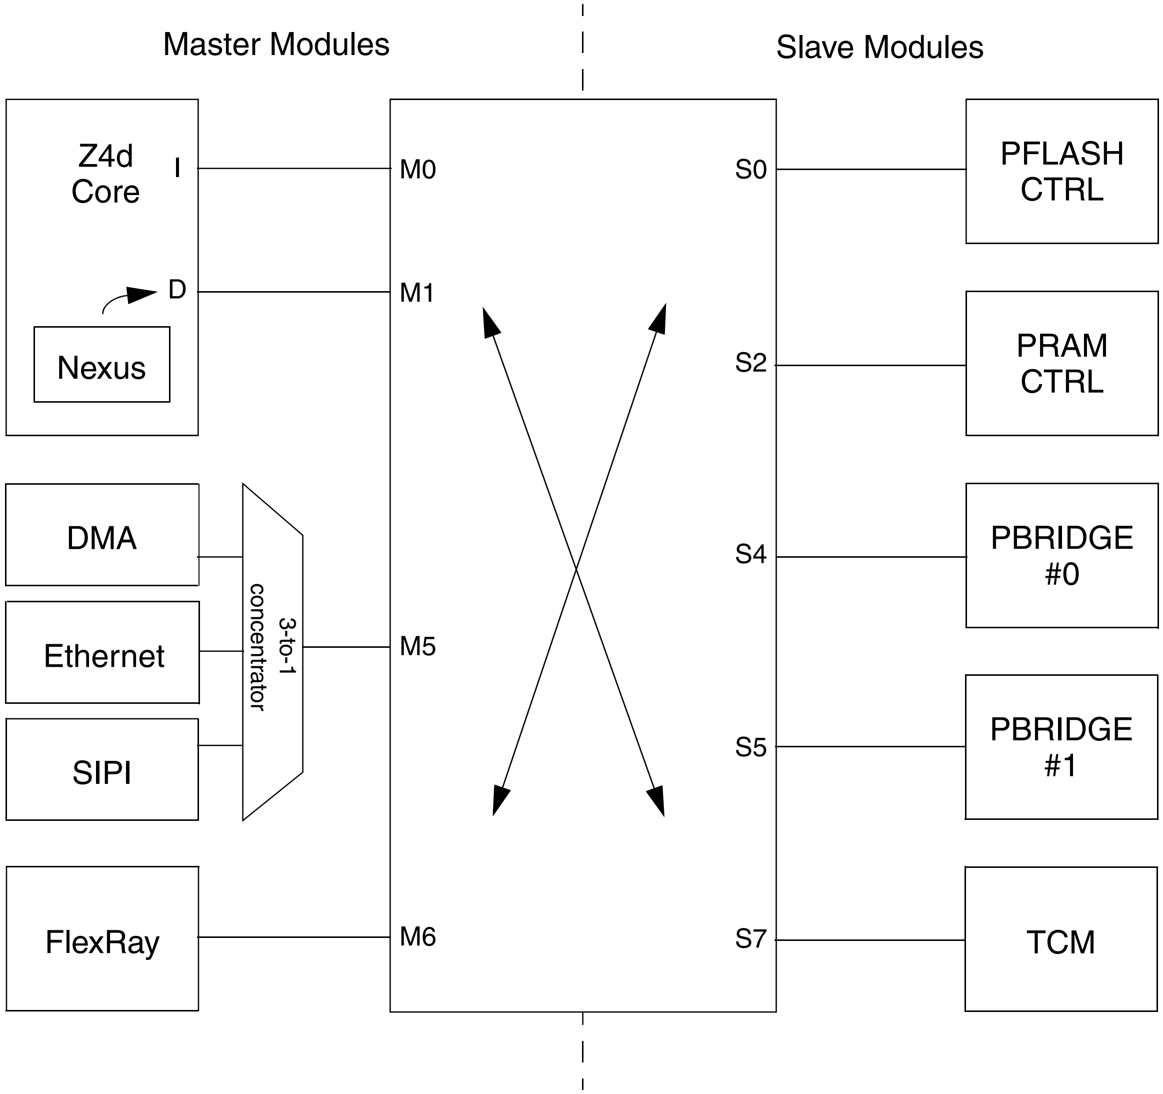

Figure 7-1. Crossbar Switch Integration

7.4.3.1 High priority requests

Each slave on the Crossbar Switch has a CRS register with an HPE field for each master. When a particular HPE field is 1, the Crossbar Switch allows the corresponding master to send high priority requests.

However, not all masters are capable of enabling high priority requests. On this device, FlexRay is the only master that enables high priority requests. The modules that are assigned to the other physical master ports have CRSx[HPEn] fields, but those modules are not capable of enabling high priority requests.

7.4.3.2 Unimplemented PRS and CRS registers

These registers are not implemented because the corresponding slave ports (1, 3, and 6) of the Crossbar Switch are not connected:.

- PRS1, PRS3, and PRS6
- CRS1, CRS3, and CRS6

7.4.3.3 Reset value of PRS and CRS registers

The reset value of the Crossbar Switch's PRS registers is 0320_0010h.

The reset value of the Crossbar Switch's CRS registers is 0000_0000h.

7.4.3.4 Logical master IDs

The following table defines the logical master IDs used by the bus masters connected to the Crossbar Switch.

Table 7-8. Logical master IDs

Master	Logical master ID
z4d_0 core complex Instruction port z4d_0 core complex Load/Store port	0
DMA	2
FlexRay	3
SIPI	4
Ethernet	5
z4d_0 core Nexus	8

7.4.3.5 Port allocation

The following table defines the master port allocation. The ports M2, M3, M4, and M7 are not connected.

Table 7-9. Crossbar Switch master port allocation

Master port	Connected master	Comments
M0	z4d_0 core complex Instruction port	
M1	z4d_0 core complex Load/Store port z4d_0 core Nexus port	Nexus also uses the Load/Store port
M5	DMA/SIPI/Ethernet	Output of the 3-to-1 concentrator
M6	FlexRay	

The following table defines the slave port connections. The ports S1, S3, and S6 are not connected.

Table 7-10. Crossbar Switch slave port allocation

Slave port	Connected slave	Comments
S0	PFLASHC	Platform Flash Memory Controller
S2	PRAMC	Platform SRAM Controller
S4	PBRIDGE0	Peripheral Bridge #0
S5	PBRIDGE1	Peripheral Bridge #1
S7	Data Local Memory	Backdoor access to Data Tightly Coupled Memory (Data TCM)

7.4.4 System Memory Protection Unit (SMPU) configuration

Memory protection isolates user and supervisor tasks through region descriptors that define access control rights. The device provides three layers of memory protection:

1. Processor core memory protection (CMPU) in the core, typically for the core's local memories (DMEM)
2. **System Memory Protection Unit (SMPU)** on the slave side of the crossbar switch
3. Peripheral access control registers (PACRs) for each address space slot in the PBRIDGE

For the second layer of memory protection, this device contains one instance of the SMPU.

The SMPU splits the physical memory into 16 different regions. Each master can be assigned different access rights to each region.

- 16 region MPU with concurrent checks against each master access
- 32 byte granularity for protected address region

See Logical master IDs for master assignments and System Memory Protection Unit (SMPU) for a detailed description of the module.

7.4.5 Peripheral Bridge configuration

The peripheral bridge (PBRIDGE or AIPS) modules are used to access the registers of most of the modules on this device.

7.4.5.1 Number of peripheral bridges

This device contains two identical peripheral bridge instances.

7.4.5.2 Memory maps

See the Memory Map for the memory slot assignment for each module.

7.4.5.3 MPRA register

Each Peripheral Bridge's MPRA register contains fields for each Crossbar Switch master on the chip.

The fields of the MPRA register apply to logical master IDs, not physical port numbers. The settings of MPRA's MTR0, MTW0, and MPL0 fields apply to both logical master 0 and logical master 8.

See Logical master IDs for the master ID assignments on this chip.

7.4.5.4 PACR/OPACR registers

The peripherals attached to the peripheral bridges each are assigned to a memory map slot that corresponds to a peripheral bridge register field. Every on-platform peripheral has an assigned PACRn field within the PACRA to PACRH registers, and every off-platform peripheral has an assigned OPACRn field within the OPACRA to OPACRAF registers.

The following tables provide the peripheral slot assignments for this device. Unused PACRn fields are reserved.

PACRH	0x0000_0000	0x0000_0000
OPACRA (OPACR0 to OPACR7) to OPACRAF (OPACR248 to OPACR255)	0x4444_4444	0x4444_4444

7.4.6 Interrupt Controller (INTC) configuration

This device contains one Interrupt Controller (INTC).

7.4.6.1 INTC number of processors and monitors

7.4.6.1.1 Number of processors

The INTC on this chip supports one processor. It is designated processor 0 in the dedicated INTC chapter.

Any information about other processor core numbers in the INTC's chapter does not apply. For example, INTC register details for other processor core numbers are reserved on this chip.

7.4.6.1.2 Interrupt Controller Monitor (INTCM)

The INTC on this chip supports one monitor because the chip has only one core. The INTCM monitors three interrupts.

7.4.6.2 Interrupt vector assignments

The following table defines the interrupt sources for the INTC on the device. All IRQ numbers that are not specifically listed are not used.

Table 7-16. Interrupt vector table

7.4.6.3 INTC software vector mode and hardware vector mode

This information supplements and clarifies the information in these other locations:

- Interrupt Vector Prefix Registers (IVPR)
- Software vector mode
- Hardware vector mode

7.4.6.3.1 Vector table alignment

On this chip, the vector table must be aligned to 64 KB.

7.4.6.3.2 INTC software vector mode

In software vector mode, software—that is, the interrupt exception handler—reads an INTC register to obtain the vector associated with the interrupt request to the processor. The INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0) contains a 32-bit address composed of a vector table base address (VTBA) plus an offset that is the interrupt vector (INTVEC). The address is used to branch to the corresponding routine for that peripheral or software interrupt source.

The following figure shows a typical program flow for software vector mode.

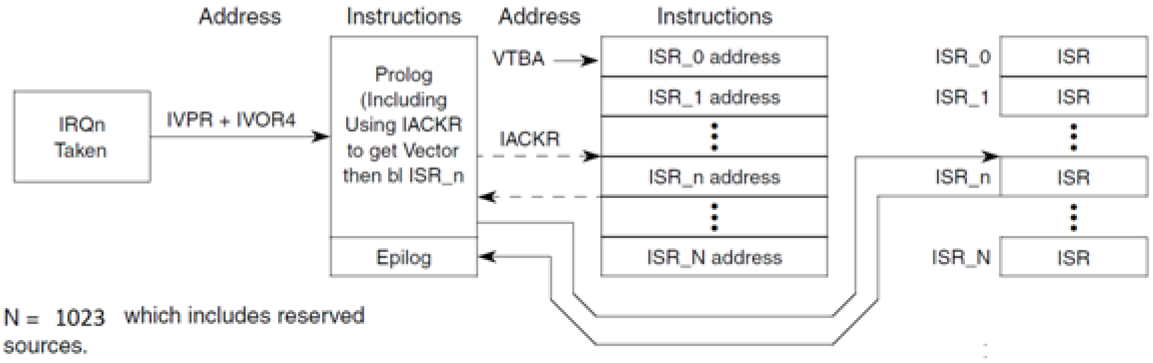

Figure 7-2. Software vector mode: program flow

In software vector mode, hardware calculates a common interrupt exception handler address as shown in the following figure. The upper part of the Interrupt Vector Prefix Register (IVPR) is added to the Interrupt Vector Offset Register 4 (IVOR4) offset.

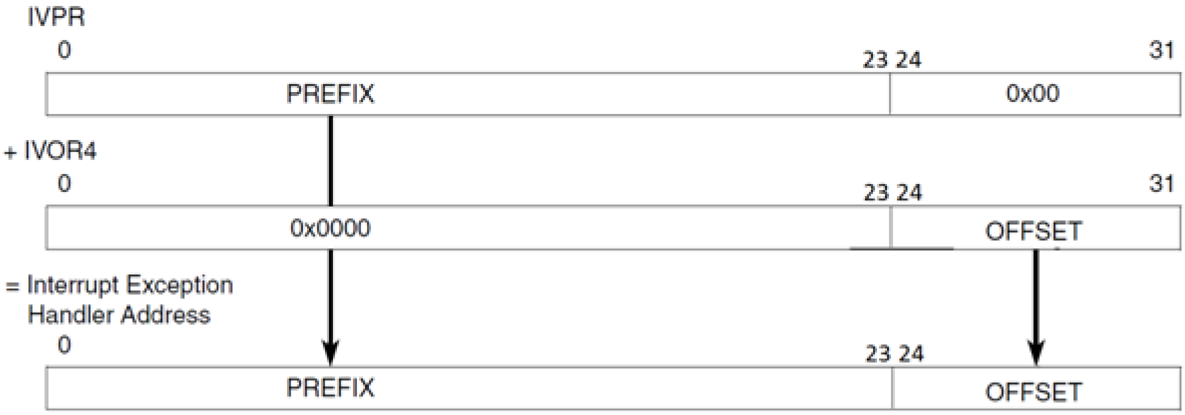

Figure 7-3. Software vector mode: interrupt exception handler address calculation

IVPR should be aligned to 256 bytes in software vector mode.

7.4.6.3.3 INTC hardware vector mode

In hardware vector mode, no Interrupt Vector Offset Register (IVOR) is used.

The following figure shows a typical program flow for hardware vector mode.

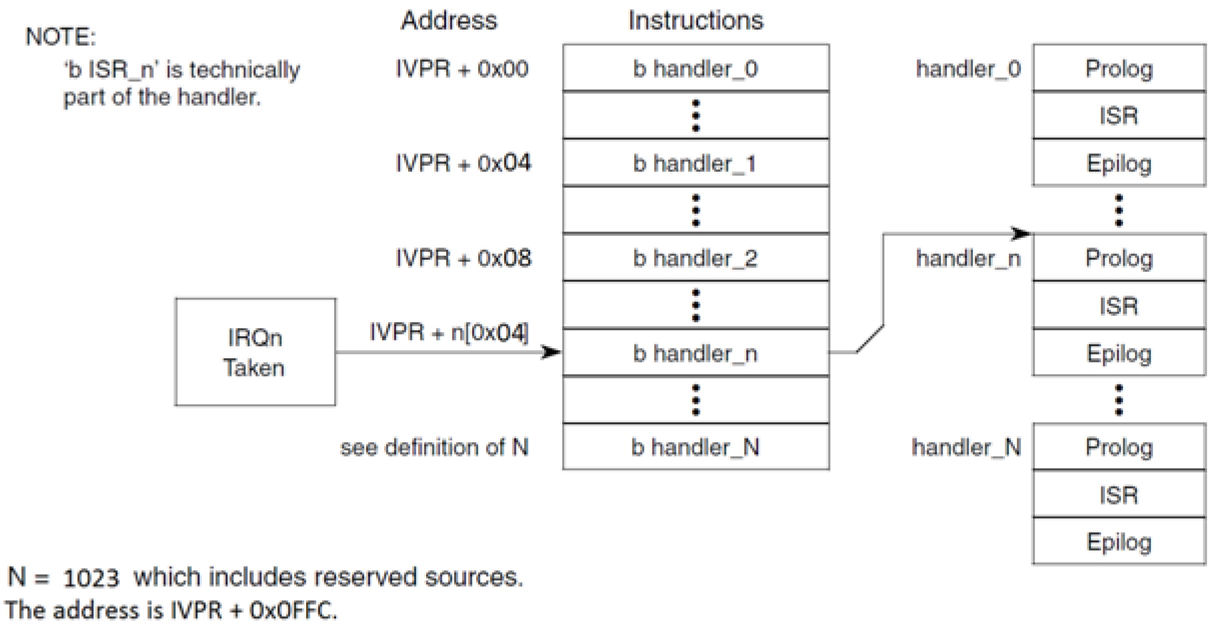

Figure 7-4. Hardware vector mode: program flow

In hardware vector mode, hardware calculates the interrupt exception handler address as shown in the following figure.

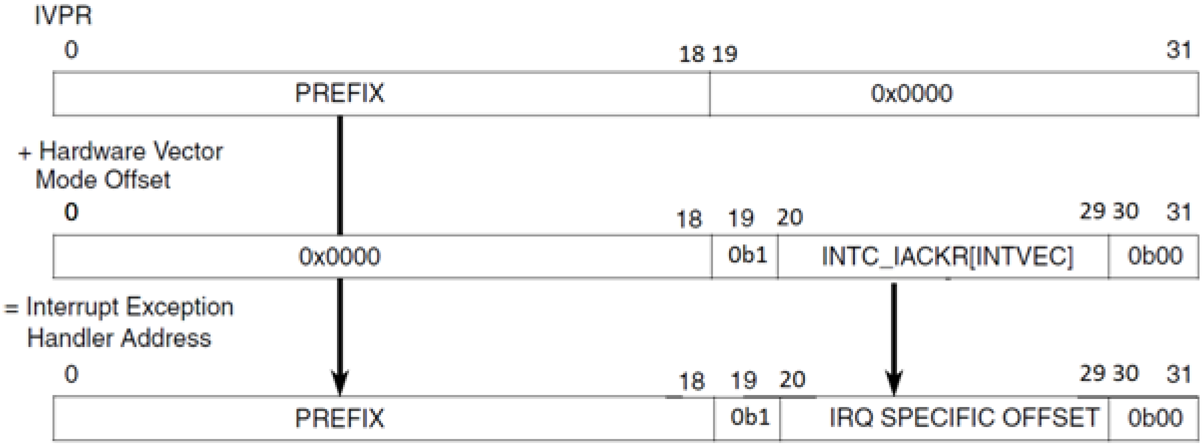

Figure 7-5. Hardware vector mode: interrupt exception handler address calculation

IVPR should be aligned to 8 KB in hardware vector mode.

7.4.7 DMA Controller configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

The device implements two 32-channel DMA controllers: DMA_0 and DMA_1. They are located in different peripheral lakes at the same location in the memory map, for redundancy.

DMA_1 is implemented in delayed lockstep using the same methodology as for the delayed lockstep of the cores:

- Only one DMA RAM array, which is accessed by DMA_0 only for read and write accesses
- DMA_1 is not visible to software. It cannot explicitly be accessed.
- DMA_1 operates with a delay of 2 cycles compared to DMA_0.
- The outputs of DMA_0 and DMA_1 are compared by RCCUs.
- The CORE_1 and DMA_1 are placed into the same lake.

For a comprehensive description of the DMA Controller, see its dedicated chapter.

7.4.8 DMAMUX configuration

This device contains two DMAMUX modules. DMAMUX_0 connects directly to DMA channels 0-15. DMAMUX_1 connects directly to DMA channels 16-31.

The DMAMUX does not generate any interrupt signals.

7.4.8.1 DMAMUX trigger inputs

The following table defines the signal sources for the trigger support of the first #TRG channels of the DMAMUX module. The table is valid for both instantiations of the module, DMAMUX_0 and DMAMUX_1.

Table 7-17. DMAMUX trigger sources

Source module	Source signal	DMAMUX channel trigger #
PIT	Trigger channel 0	0
PIT	Trigger channel 1	1
PIT	Trigger channel 2	2
PIT	Trigger channel 3	3

7.4.8.2 DMA request source slot mapping

The following tables define the mapping of the DMAMUX source slots to the interrupt request sources on the device.

Together, DMAMUX_0 and DMAMUX_1 support the total number of source slots documented in the dedicated DMAMUX chapter.

Table 7-18. DMAMUX_0 source slot mapping

DMAMUX source slot #	Source module	Source resource
1	DSPI_2	DSPI_TFFF
2	DSPI_2	DSPI_RFDF

7.4.9 Error Injection Module (EIM) configuration

The EIM provides error injection for the DMA memory Error Correcting Code (ECC).

7.5 Clocking

See the Clocking chapter for a description of the architecture for system level clocks, including clock generation, clock sources, and peripheral clocks. The chapter also provides configuration details for the Clock Monitor Unit (CMU).

7.6 Memories and memory interfaces

See the chapters shown in the following table for detailed information about memories and memory interfaces.

Table 7-20. Reference links to related information

Topic	Reference
Embedded memories	Embedded memories
System memory map	Memory Map
Platform Flash Memory Controller	Flash Memory Controller
Platform RAM Controller	RAM Controller (PRAM)
Embedded flash memory	Embedded Flash Memory (c55fmc)

7.6.1 RAM controller (PRAMC) configuration

7.6.1.1 PRAMC optional read wait states

The following table shows programming values for the Pn_BO_DIS and FT_DIS fields of the PRAMC's PRCR1 register and the resulting access timing for a WRAP4 burst. For additional information, see Optional read wait-state.

Table 7-21. Read wait states for WRAP4 burst

P0_BO_DIS or P1_BO_DIS	FT_DIS	WRAP4 timing
0	0	2/3-2-2-2
0	1	3/4-2-2-2
1	0	2/3-2-2-2
1	1	3/4-4-4-4

Programming additional, optional wait states is not required except as needed for debug.

7.6.2 Flash Memory Controller (PFLASH) configuration

The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three of the registers, PFCR1, PFCR2, and PFAPR, control the interaction of master modules with the flash array by enabling/disabling prefetch or by controlling access to the flash array on a per-master basis.

Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on. See Logical master IDs for master assignments.

NOTE

ECC events encountered when the flash is in UTest mode are not subsequent to an externally-requested read operation. Margin Read and Array Integrity checks are strictly internal to the C55FMC flash and, as stated in the flash chapter, the results are combined by a MISR into a signature. ECC events during UTest activity are not reported externally to the flash.

See the PFCR3 register details in the flash memory controller chapter for more details on configuring the flash controller.

7.6.2.1 PFLASH interface to SRAM as overlay RAM

The PFLASH serves as the interface to the on-chip SRAM, which can be used as overlay RAM.

7.6.3 Embedded Flash Memory (c55fmc) configuration

7.6.3.1 C55FMC register reset values

The following table lists C55FMC register reset values that are specific to this chip. For the reset values of all other C55FMC registers, see Memory map and register definition.

Table 7-22. Chip-specific C55FMC register reset values

Register	Reset value
Extended Module Configuration Register (C55FMC_MCRE)	0460_0802h[1]
Over-Program Protection 0 register (C55FMC_OPP0) Over-Program Protection 1 register (C55FMC_OPP1) Over-Program Protection 2 register (C55FMC_OPP2) Over-Program Protection 3 register (C55FMC_OPP3)	See Flash OTP Control.

[1] This value applies for MPC5744P, MPC5743P, MPC5742P, and MPC5741P.

7.6.3.2 C55FMC_LOCK*n* register bit mapping

The C55FMC_LOCK*n* registers provide a means to protect flash memory blocks from being modified. Each implemented bit in a C55FMC_LOCK*n* register maps to a specific block.

7.6.3.2.1 C55FMC_LOCK0 register bit mapping

The flash memory blocks mapped to the Lock 0 register (C55FMC_LOCK0) bits are as follows.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

7.6.3.4 C55FMC_OPP*n* register bit mapping

The C55FMC_OPP*n* registers provide a means to protect blocks from being over-programmed. Each implemented bit in a C55FMC_OPP*n* register maps to a specific memory block.

7.6.3.4.1 C55FMC_OPP0 register bit mapping

The flash memory blocks mapped to the Over-Program Protection 0 register (C55FMC_OPP0) bits are as follows.

7.6.4 Decorated Storage Memory Controller (DSMC) configuration

The DSMC supports five store and three load operations, including:

Bit field inserts
Compare-and-store
Bitwise AND, OR, and XOR operators
Simple memory load
Swap
Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The module includes error checking logic that validates the decoration field, ensuring it is properly defined: all illegal commands are rejected and the transfer error is terminated. Additionally, the decorated storage memory controller only operates on aligned, single data transfers. Misalignment and/or bursts are not supported and, if attempted, are error terminated.

The DSMC is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The device DSMC controllers are instantiated for SRAM, PBRIDGE_0, and PBRIDGE_1. The access size is forced to 64-bit for SRAM and 32-bit for the PBRIDGE modules.

7.7 Motor control configurations

This section provides information regarding various frequency combinations that can be used depending on the used case. The table shown below gives the valid CGM configurations for motor control subsystem.

Table 7-23. Valid CGM configurations for motor control subsystem

Clock domain	Config 1	Config 2	Config 3	Config 4
SYS_CLK	PLL1_200 MHz	PLL1_200 MHz	PLL1_200 MHz	PLL0_200 MHz
AC0_DC0 (ADC aux clk divider)	PLL0_160 MHz	PLL1_200/2 MHz = 100 MHz	PLL0_200/2 MHz = 100 MHz	PLL0_200/2 MHz = 100 MHz
AC0_DC2 (ADC aux clk divider)	PLL0_160/2 MHz = 80 MHz	PLL1_200/4 MHz = 50 MHz	PLL0_200/4 MHz = 50 MHz	PLL0_200/4 MHz = 50 MHz

Example used cases:

- For best ADC dynamic performance, it is recommended to run with single PLL supplying both system clock and motor control clocks (either PLL1 - Config 2 or PLL0 - Config 4).
- In case dual PLL configuration is required, run at a frequency where the clocks are harmonically related (Config - 3).
- Use Config - 1, i.e PLL1 with frequency modulation to improve EMC and PLL0 with frequency modulation for noise free usage of motor control peripherals and ADC or when Flexray with 80 MHz configuration is required.

7.8 Motor control modules

This section highlights the modules for motor control that are implemented on the device.

Table 7-24. Motor control modules

Module or subsystem	Device-specific information	Block details
Temperature sensor	Temperature sensor configuration	Temperature Sensor
ADC subsystem	ADC Configuration chapter	See individual modules
Successive Approximation Register Analog-to-Digital Converters (SAR ADCs)	ADC Configuration chapter	ADC Digital (ADCD)
eTimer	Enhanced Motor Control Timer (eTimer) configuration	Enhanced Motor Control Timer (eTimer)
FlexPWM	Motor Control Pulse Width Modulator Module (FlexPWM) configuration	Motor Control Pulse Width Modulator Module (FlexPWM)
CTU	Cross-Triggering Unit (CTU) configuration	Cross-Triggering Unit (CTU)

7.8.1 Temperature sensor configuration

This device contains two Temperature Sensor modules, TSENS_0 and TSENS_1, located in different peripheral lakes.

The junction temperature sensor generates an output voltage that is directly proportional to the internal junction temperature of the device. The information provided by this sensor can be used to implement some intelligent power control (such as to reduce frequency when temperature is too high).

The mapping of the two temperature sensors to the ADC channels is defined in the ADC Configuration details. The temperature sensor has no input signals. Out of bounds detection of the chip temperature is handled via:

- A/D conversion of the analog values of both temperature sensors and software evaluation and software-initiated action on the results.
- FCCU failure generation according to the defined low and high temperature points.

7.8.1.1 Temperature sensor registers

The Power Management Controller (PMC) module provides registers controls for the temperature sensor modules. See the chapter dedicated to the PMC.

7.8.1.2 Temperature sensor bandgap reference

The analog portion of the PMC provides the bandgap reference for the temperature sensor modules.

7.8.2 Analog to Digital Converter (ADC) configuration

See ADC Configuration.

7.8.3 Sine Wave Generator (SGEN) configuration

This chip implements one instance of the SGEN module, SGEN_0.

7.8.4 Enhanced Motor Control Timer (eTimer) configuration

This device contains three eTimer modules: eTimer_0, eTimer_1, and eTimer_2.

Each eTimer module comprises six 16-bit channels. All eTimer modules supports 5 Auxiliary Inputs. eTimer_0 supports the watchdog timer function.

All eTimers have DMA support. eTimer_0 has 4 DMA channels (channel 3,2,1,0). eTimer_1 and eTimer_2 each have 2 DMA channels (channel 1,0).

7.8.4.1 Required eTimer configuration before STOP mode entry

When ETIMER_CHn_CTRL3[STPEN] for an eTimer instance is 1: Before entering STOP mode, configure the eTimer to be stopped by programming MC_ME_PCTL137[LP_CFG] (eTimer_1), MC_ME_PCTL245[LP_CFG] (eTimer_2), or MC_ME_PCTL247[LP_CFG] (eTimer_0), as applicable, to select an MC_ME_LP_PCn configuration where MC_ME_LP_PCn[STOP0] is 0.

7.8.5 Motor Control Pulse Width Modulator (FlexPWM) configuration

This device contains two FlexPWM modules: FlexPWM_0 and FlexPWM_1.

The following table shows all signals connected to FlexPWM_0 and FlexPWM_1 input ports originating from other modules on the SoC for inter-module communication. See CTU inter-module connections for more details.

Table 7-25. FlexPWM_0 and FlexPWM_1 module-to-module input signals

Source (output ports)		Destination (input ports)	
Module name	**Port name**	**Module name**	**Port name**
eTimer_0	T1	FlexPWM_0	EXT_FORCE
eTimer_1	T1	FlexPWM_0	CLOCK
eTimer_2	T1	FlexPWM_1	EXT_FORCE
eTimer_2	T3	FlexPWM_1	CLOCK
FlexPWM_0	Master Reload (local_reload0)	FlexPWM_1	EXT_SYNC

7.8.6 Cross-Triggering Unit (CTU) configuration

This device contains two CTU modules: CTU_0 and CTU_1.

7.8.6.1 CTU inter-module connections

The following figure shows the inter-module connection of the CTUs for the Motor Control related peripherals for the device.

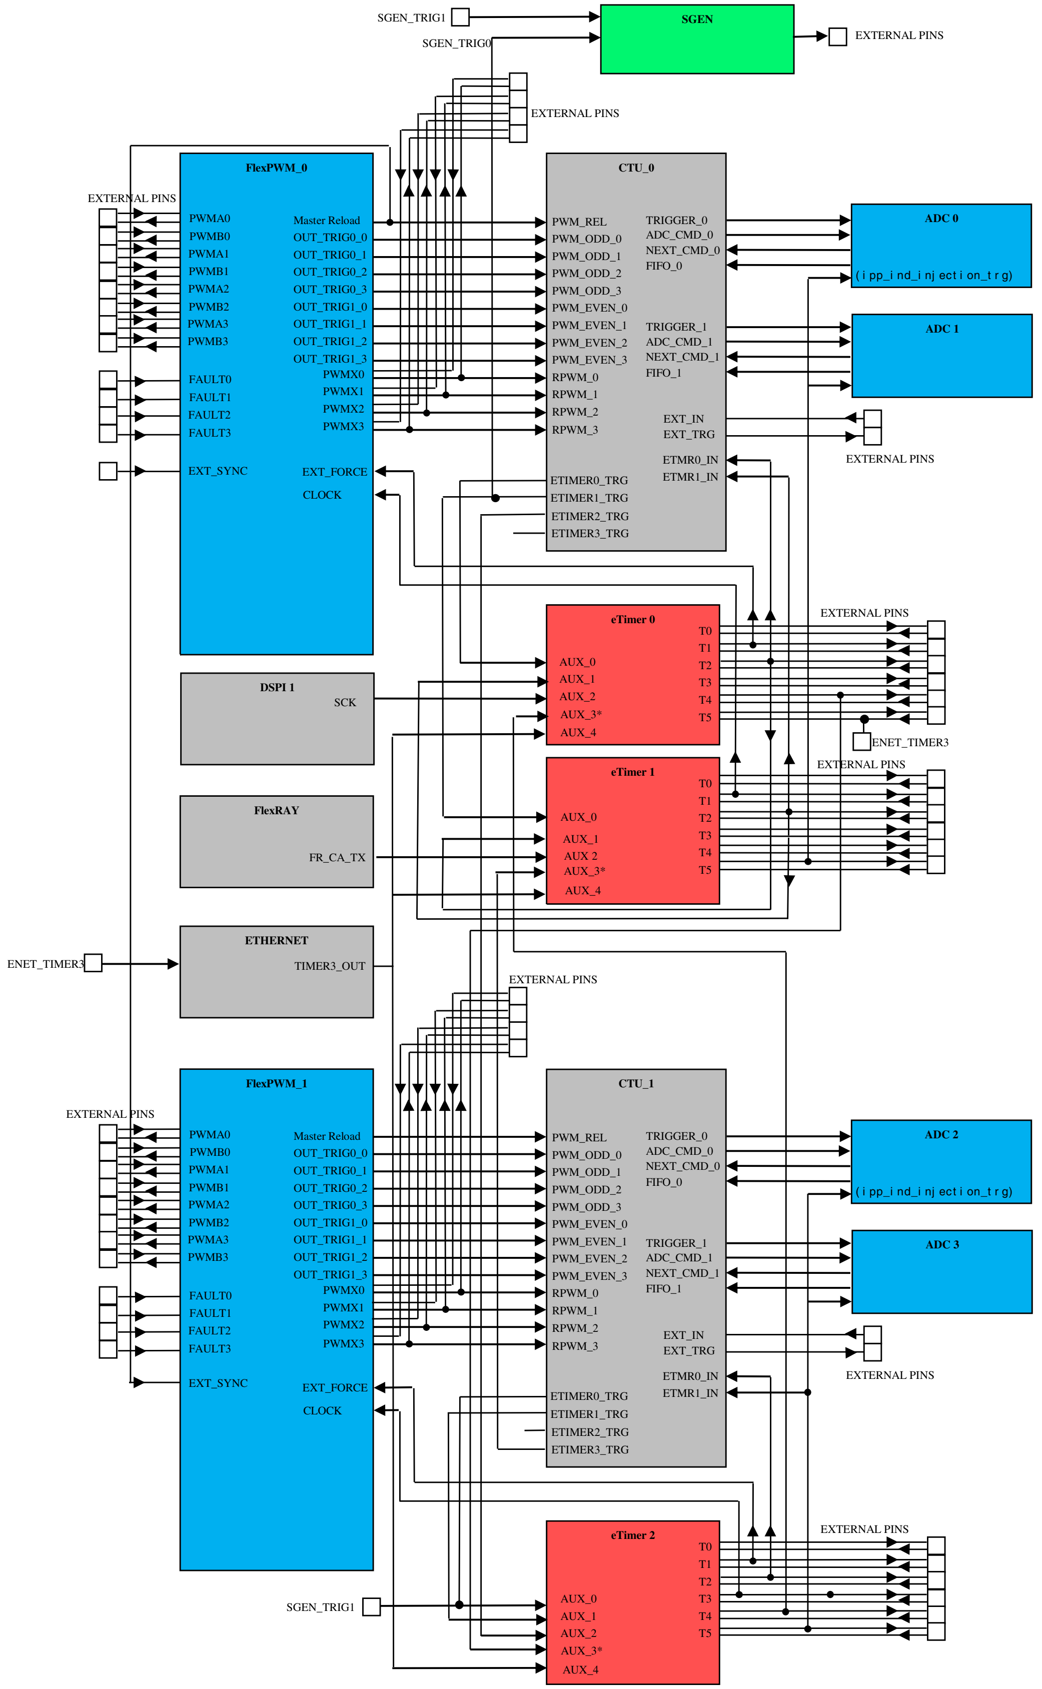

Figure 7-6. CTU inter-module connections

7.8.6.2 TGSISR input assignments for CTU_0 and CTU_1

The following table identifies the alignment among the following:

- The input number used in the I*n*RE and I*n*FE fields of the CTU's register TGSISR
- The generic name used in the CTU chapter for the CTU input with that input number
- For both CTU_0 and CTU_1, the specific source on this device for the CTU input with that input number

Table 7-26. Input assignments for CTU_0_TGSISR and CTU_1_TGSISR

Input	TGSISR fields	CTU generic input name	CTU_0_TGSISR source	CTU_1_TGSISR source
0	I0RE and I0FE	PWM_REL	FlexPWM_0 Master Reload	FlexPWM_1 Master Reload
1	I1RE and I1FE	PWM_ODD_0	FlexPWM_0 OUT_TRIG0_0	FlexPWM_1 OUT_TRIG0_0
2	I2RE and I2FE	PWM_ODD_1	FlexPWM_0 OUT_TRIG0_1	FlexPWM_1 OUT_TRIG0_1
3	I3RE and I3FE	PWM_ODD_2	FlexPWM_0 OUT_TRIG0_2	FlexPWM_1 OUT_TRIG0_2
4	I4RE and I4FE	PWM_ODD_3	FlexPWM_0 OUT_TRIG0_3	FlexPWM_1 OUT_TRIG0_3
5	I5RE and I5FE	PWM_EVEN_0	FlexPWM_0 OUT_TRIG1_0	FlexPWM_1 OUT_TRIG1_0
6	I6RE and I6FE	PWM_EVEN_1	FlexPWM_0 OUT_TRIG1_1	FlexPWM_1 OUT_TRIG1_1
7	I7RE and I7FE	PWM_EVEN_2	FlexPWM_0 OUT_TRIG1_2	FlexPWM_1 OUT_TRIG1_2
8	I8RE and I8FE	PWM_EVEN_3	FlexPWM_0 OUT_TRIG1_3	FlexPWM_1 OUT_TRIG1_3
9	I9RE and I9FE	RPWM_0	FlexPWM_0 PWMX0	FlexPWM_1 PWMX0
10	I10RE and I10FE	RPWM_1	FlexPWM_0 PWMX1	FlexPWM_1 PWMX1
11	I11RE and I11FE	RPWM_2	FlexPWM_0 PWMX2	FlexPWM_1 PWMX2
12	I12RE and I12FE	RPWM_3	FlexPWM_0 PWMX3	FlexPWM_1 PWMX3
13	I13RE and I13FE	ETIMER1_IN	eTimer_0 TO2	eTimer_2 TO2
14	I14RE and I14FE	ETIMER2_IN	eTimer_1 TO2	eTimer_2 TO5
15	I15RE and I15FE	EXT_IN	External pin	External pin

7.9 Timers

Three types of timers and a complex timer subsystem are implemented on the device.

Table 7-27. Timers

Timer	Device-specific information	Block details
System Timer Module (STM)	System Timer Module (STM) configuration	System Timer Module (STM)
Software Watchdog Timer (SWT)	Software Watchdog Timer (SWT) configuration	Software Watchdog Timer (SWT)
Periodic Interrupt Timer (PIT)	PIT configuration	Periodic Interrupt Timer (PIT)

Table continues on the next page...

Table 7-27. Timers (continued)

Timer	Device-specific information	Block details
Enhanced Motor Control Timer (eTimer)	Enhanced Motor Control Timer (eTimer) configuration	Enhanced Motor Control Timer (eTimer)

The master core has a dedicated System Timer Module (STM) and a dedicated Software Watchdog Timer (SWT).

7.9.1 System Timer Module (STM) configuration

This device contains one System Timer Module (STM).

The STM chapter states that the internal timer of the STM runs on the "system clock." On this chip, the STM's "system clock" is PBRIDGEx_CLK.

On this chip, STM_CR resets to 0000_0000h.

7.9.2 Software Watchdog Timer (SWT) configuration

This device contains one Software Watchdog Timer (SWT) module.

The internal timer of the SWT always runs on the IRCOSC clock.

The user must configure the outcomes of SWT time-out events by programming ITR in the SWT_CR as well as FCCU reactions to associated non-critical faults (NCFs):

- When SWT_CR[ITR] is 0, any SWT time-out generates a reset request that corresponds to NCF[14].
- When SWT_CR[ITR] is 1:
  - An initial time-out generates an interrupt request and triggers NCF[72].
  - A second consecutive time-out generates a reset request that corresponds to NCF[14].

CAUTION

To ensure that NCF[14] results in a reset, configure the FCCU’s reaction to NCF[14] to be a long functional reset or short functional reset.

7.9.3 Periodic Interrupt Timer (PIT) configuration

This device contains one Periodic Interrupt Timer (PIT) module.

The PIT contains four 32-bit timer channels. Four channels are used as trigger timer for DMAMUX.

NOTE

For valid PIT clock frequency for this device please refer to Figure 13-3 and Table: Maximum system level clock frequencies.

7.10 Communication interfaces

7.10.1 FlexCAN configuration

This device contains three Controller Area Network (CAN) modules: FlexCAN_0, FlexCAN_1, and FlexCAN_2. Each FlexCAN instantiation supports 64 Message Buffers.

Each FlexCAN module supports programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator.

Each FlexCAN module sources 11 interrupt vectors.

Each FlexCAN module has one external output CAN_Tx (CAN Transmit) and one external input CAN_Rx (CAN Receive).

7.10.1.1 FlexCAN interrupt flag ERRSR[CEIF]

The interrupt flag ERRSR[CEIF] does not have an assigned vector and does not generate an interrupt because the error it flags is corrected automatically. Nevertheless, ERRSR[CEIF] can be used as a status flag to report single-bit correctable memory errors.

7.10.2 LVDS Fast Asynchronous Transmission (LFAST) interface configuration

This device contains one LFAST interface.

The LFAST module is used to transfer data and control information between two devices (Master and Slave), and is capable of supporting either Dual mode (for example, configurable Master/Slave) or Slave-only mode functionality.

The serial link can run at up to 320 MBit/s using an LVDS physical layer. The following external signals are needed:

- One LVDS pair for Tx
- One LVDS pair for Rx
- Reference voltage pad
- Separate reference clock signal (not LVDS)

The LFAST Tx and Rx lines are connected to the pads via the SIUL2 and the MSCR registers. The Tx Data Port/Rx Data Port is connected to the SIPI module. The LFAST supports five interrupts.

The LFAST implementation includes a dedicated PLL for multiplying a low-speed clock source up to 320 MHz for the transmission and reception of data. The high-speed asynchronous nature of LFAST requires that both the local node and remote node operate from the same stable, low-jitter clock sources. This common low-speed clock is referred to as the Reference Clock.

7.10.3 Serial Peripheral Interface (SPI) configuration

This chip has four SPI module instances.

- None of the instances supports or uses these features:
  - Deserialization (DSI)
  - Global interrupt request line
- SPI_0 and SPI_1 each support 8 chip selects. SPI_2 and SPI_3 each support only 4 chip selects.

The terms SPI and DSPI are used interchangeably in this document.

7.10.4 FlexRay configuration

This device contains one dual channel FlexRay module with 64 configurable message buffers. The FlexRay module provides the following features:

- Protocol implementation compliant with FlexRay Communications System Protocol Specification, Version 2.1 Rev A
- Bus driver interface compliant with FlexRay Communications System Electrical Physical Layer Specification, Version 3.0
- Can be configured for single channel

- FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B
- Support for FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s

7.10.4.1 FlexRay interrupts

The FlexRay module provides seven individual interrupt sources and five combined interrupt sources. The following table describes all twelve interrupt sources.

- Eight interrupt sources are routed to the INTC.
- Two interrupt sources indicating correctable ECC errors of the local SRAM are combined (ORed) and then routed to the INTC. One of these two is also routed to the MEMU.
- Two interrupts indicating non-correctable ECC errors of the local SRAM are routed individually to the MEMU as well as combined (ORed) and routed to the INTC.

Table 7-28. FlexRay interrupts

Interrupt name	Register field	FlexRay module internal IRQ type	Connected to
Receive FIFO Channel A Not Empty Interrupt	FNEAIF	Individual	INTC
Receive FIFO Channel B Not Empty Interrupt	FNEBIF	Individual	INTC
Wakeup Interrupt	WUPIF	Individual	INTC
Protocol Status and Error Interrupt	PRIF	Combined	INTC
CHI Error Interrupt	CHIF	Combined	INTC
Transmit Message Buffer Interrupt	TBIF	Combined	INTC
Receive Message Buffer Interrupt	RBIF	Combined	INTC
Module Interrupt	MIF	Combined	INTC
LRAM Correctable ECC Error Interrupt	LRCEIF	Individual	INTC
DRAM Correctable ECC Error Interrupt	DRCEIF[1]	Individual	INTC, MEMU
LRAM Non-correctable ECC Error Interrupt	LRNEIF	Individual	INTC, MEMU
DRAM Non-correctable ECC Error Interrupt	DRNEIF[2]	Individual	

[1] These two individual interrupt sources are combined (logical OR) before being routed to the interrupt controller.

[2] These two individual interrupt sources are combined (logical OR) before being routed to the interrupt controller. They are routed individually to the MEMU.

7.10.4.2 FlexRay external signals

Table 7-29. FlexRay external signals

Signal name	Direction	Signal description
FR_A_TX	Output	FlexRay Channel A Transmit
FR_A_TX_EN	Output	FlexRay Channel A Transmit Enable: active low

Table continues on the next page...

Table 7-29. FlexRay external signals (continued)

Signal name	Direction	Signal description
FR_A_RX	Input	FlexRay Channel A Receive
FR_B_TX	Output	FlexRay Channel B Transmit
FR_B_TX_EN	Output	FlexRay Channel B Transmit Enable: active low
FR_B_RX	Input	FlexRay Channel B Receive
FR_DBG[3:0]	Output	Debug/Strobe Output (shared with GPIO)

7.10.5 SENT receiver (SRX) configuration

The Single Edge Nibble Transmission (SENT) module is designed as a receiver for transmitting sensor nodes using the SENT protocol (as documented by the SAE J2716 information report). SENT is a unidirectional communications scheme from a sensor (transmitting) device to a controller (receiving) device that does not include a coordination signal from the controller/receiving device.

This device contains two SENT modules. Each has two channels. The two modules are distributed to the two peripheral subsystems to allow redundancy for safety applications. The SENT has interrupts for slow and fast messages. There are two DMA requests per instantiated SENT module for the fast and slow messages. The SENT FIFO depth is 4.

The 5.0 V power supply required for a SENT interface is not provided by the MCU. This supply must be provided externally as shown in SAE J2716. As a result, the SENT has only one receive input pad per channel.

7.10.6 LINFlexD configuration

This device contains two LINFlex peripherals: LINFlex_0 and LINFlex_1. They are distributed between the two AIPS peripheral sub system for safety reasons.

The LINFlex module supports master and slave mode, contains one TX and one RX channel, and contains 16 identifier filtering in hardware.

Each LINFlex module can generate interrupts (RX, TX, Error). TX and RX have DMA channels.

The LINFlex baud rate clock is half the system clock. For example: When the system clock is 200 MHz, the LINFlex baud rate clock is 100 MHz.

7.10.7 Ethernet (ENET) configuration

The ENET module is connected to the eTimer modules. See the CTU inter-module connections diagram.

NOTE

> Before making any access to the Ethernet registers make sure the ENET module clock is enabled. If not, it is possible for the system to stall instead of generating a bus error.

The ENET module connects to external timer signals. See the Clocking chapter for details.

The ENET module's RMII_CLK can be output on Port Pin G[8]. Along with configuring the SIUL2_MSCR104 for selecting the ENET_0[RMII_CLK] function on Port Pin G[8], the user also needs to configure GCR[RMII_CLK_EN].

7.10.7.1 Generic Control Register (GCR)

	0xFFC0_C000																															
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																										RMII_CLK_EN	Reserved				
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Field	Description
0 - 25 Reserved	This field is reserved.
26 RMII_CLK_EN	Configuration bit that must be programmed along with SIUL2_MSCR[104] to enable RMII_CLK on pad[104] (Port Pin G[8]). 0 - RMII_CLK (Aux Clock 10) is not output on pad[104] (Port Pin G[8]) 1 - RMII_CLK (Aux Clock 10) is output on pad[104] (Port Pin G[8])
27 - 31 Reserved	This field is reserved.

7.11 Reset and boot modules

7.11.1 System Status and Configuration Module (SSCM) configuration

There is one SSCM instance in the device. The SSCM is part of the reset and boot subsystem.

NOTE

UART and SCI are used interchangeably in the document beyond this point.

7.11.1.1 SSCM_MEMCONFIG reset value

On the production-intent version of the chip, these MEMCONFIG fields have the indicated reset values:

- MREV: 2h
- JPIN: 2C5h

7.11.1.2 SSCM_UOPS register and soc_conf DCF client

On this device, two fields in the SSCM_UOPS register perform a specific function on the device. The other fields in the register are reserved.

The DCF client soc_conf provides the value of the SSCM_UOPS fields. For information about modifying soc_conf, see Device Configuration Format (DCF) Records.

The following table defines the two fields and shows their bit positions in both the register and the DCF client.

Table 7-30. SSCM_UOPS and soc_conf fields

Field	SSCM_UOPS bit position	soc_conf bit position	Default value	Function of default value
Checker Core Enable (CCE)	2	31	1	Enables checker core[1]
Watchdog Enable (WDE)	0	30	0	Enables watchdog automatically after device exits reset

[1] Turn off checker core for power saving or debug

7.11.1.3 UTEST_OFFSET location

On this device, the UTEST_OFFSET location at which the SSCM looks for UTEST DCF records is 0040_0200h.

7.11.1.4 SSCM_ERROR[RAE] exception not produced for some modules

Setting RAE in the SSCM Error Configuration Register (SSCM_ERROR) to 1 produces a Prefetch or Data Abort exception for illegal accesses to most off-platform peripherals.

However, for a subset of off-platform peripherals, illegal accesses to unimplemented spaces in the peripherals' memory maps do not produce a Prefetch or Data Abort exception. This subset includes the CMUs, SIPI, FCCU and CTU.

7.11.1.5 SSCM boot locations in flash memory

Table 5-4 identifies the boot locations in flash memory that contain a valid RCHW record.

7.12 Safety modules

7.12.1 CRC configuration

The value of the parameter CRC_CNTX_NUM, which defines the number of application contexts and therefore the number of instances of CRC registers, is 3.

7.12.2 Memory Error Management Unit (MEMU) configuration

The following diagram shows the data flow of the various Error Correction Code logic used for the Flash, System RAM and the Peripheral RAMs.

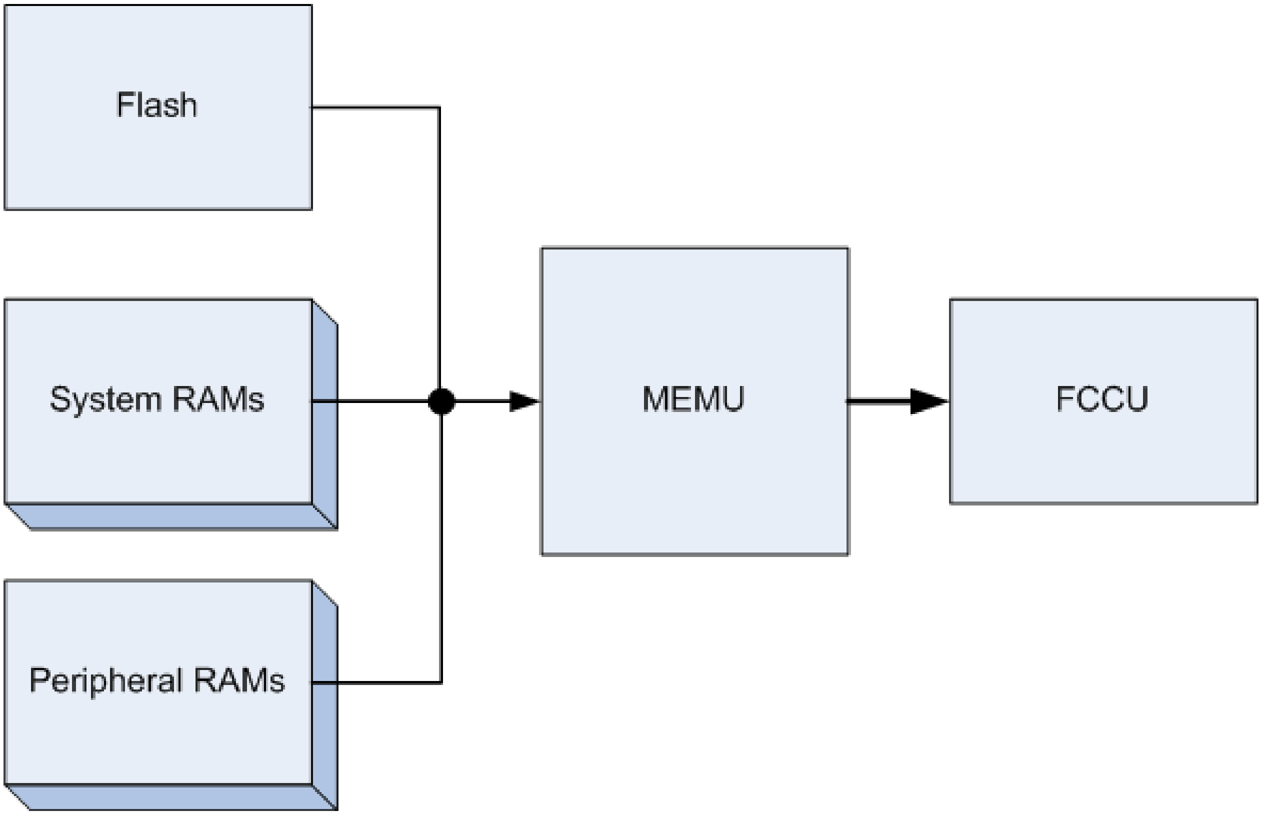

Figure 7-7. MEMU System Connections

7.12.2.1 Error sources for Concurrent Overflow (OFLWn) registers

The three categories of error reporting for the MEMU are:

- System RAM error reporting: Any RAM that is CPU accessible falls into this category.
- Peripheral RAM error reporting: Any RAM that is not CPU accessible falls into this category.
- Flash error reporting

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLWn register details the corresponding error source to the respective field in the Concurrent Overflow registers.

Table 7-31. Corresponding error sources for OFLWn registers

Memory	Memory Classification	ECC: Single Error Correcting (SEC) or Double Error Detecting (DED)	OFLW register: <bit position>
Core 0			
Core D-MEM CPU0	System RAM	SEC/DED	MEMU_SYS_RAM_OFLW0: bit 0
Core I-Cache	System RAM	SEC/DED	MEMU_SYS_RAM_OFLW0: bit 1

Table continues on the next page...

Table 7-31. Corresponding error sources for OFLWn registers (continued)

Memory	Memory Classification	ECC: Single Error Correcting (SEC) or Double Error Detecting (DED)	OFLW register: <bit position>
Core D-Cache[1]	System RAM	SEC/DED	MEMU_SYS_RAM_OFLW0: bit 2

[1] Cache tag errors can be single-bit or double-bit. Cache data array errors are reported as single-bit errors only, regardless of the number of errors reported, since the logic does not exist in the cache to distinguish them.

7.12.2.2 Uncorrectable error in flash memory can cause uncorrectable error in SRAM

Be aware of the following scenario where an uncorrectable error in flash memory can cause an uncorrectable error in SRAM to be reported. Each error triggers a separate FCCU response.

1. An uncorrectable error in flash memory occurs, and C55FMC_MCR[EER] sets to 1.
2. MEMU_FLASH_UNCERR_STS[VLD] sets to 1, and
   MEMU_ERR_FLAG[F_UCE] sets to 1.
   MEMU_FLASH_UNCERR_ADDR[ERR_ADD] records the address on which the error was detected.
3. The FCCU responds to a fault on NCF[22].

When the core register field E2ECTL0[DECCEN] is 1, these events follow:

1. The detected error in flash memory results in an exception/machine check.
2. MEMU_SYS_RAM_UNCERR_STS[VLD] sets to 1, and
   MEMU_ERR_FLAG[SR_UCE] sets to 1.
   MEMU_SYS_RAM_UNCERR_ADDR[ERR_ADD] records the address on which the error was detected.
3. The FCCU responds to a fault on NCF[16].

7.12.2.3 FlexCAN RAM error address must be shifted left twice

When a correctable or uncorrectable error occurs in a FlexCAN module's peripheral RAM, the error address captured in the MEMU_PERIPH_RAM_CERR_ADDRn or MEMU_PERIPH_RAM_UNCERR_ADDRn register is incorrect. Shift the captured address left twice to determine the actual address.

7.12.3 Fault Collection and Control Unit (FCCU) configuration

7.12.3.1 Fault inputs

Table 7-33 shows the source of the fault signals and the type of fault input to which these signals are connected at the FCCU..

All faults are marked as non-critical faults (NCF) input at the FCCU. FCCU can set reaction of each faults as critical or non-critical faults reaction. Unmasked faults with the time-out disabled are treated like critical faults by the FCCU. Table 7-32 explains the conventions used in the "Set/Clear injection" column of Table 7-33.

Table 7-32. Set/Clear injection conventions

Convention	Explanation
—	Set/clear is not supported by writing to FCCU NCF Fake Register (FCCU_NCFF)
Clear	Can be cleared only, not set, by writing to FCCU NCF Fake Register (FCCU_NCFF)
X	Can be set and cleared by writing to FCCU NCF Fake Register (FCCU_NCFF)
X (by ADC itself)	Can be set/cleared by writing to STCR2[SERR] of the applicable ADC instead of writing to FCCU NCF Fake Register (FCCU_NCFF)
X (by PMC itself)	Can be set/cleared by writing to the applicable bit of PMC_FIR instead of writing to FCCU NCF Fake Register (FCCU_NCFF)

Table 7-33. FCCU Non-Critical Faults Mapping

NCF[73]	PMC DCF	Digital PMC initialization error during DCF data load (status is cleared if the fault is not persistent)	—	X	X
NCF[74]	FCCU DCF	Misconfiguration of error_out pin interface of the FCCU after reset (overwriting the respective configuration bits resolves this error)	—	X	X

1. See Table 1 for an explanation of this column's contents.
2. Function not available on module
3. This fault is not generated in debug mode because the RCCUs are disabled in debug mode. See Core lockstep and RCCU disablement in debug mode for more information.
4. Always configure the FCCU reaction to NCF[14] as a short or long functional reset. Never configure it as an interrupt.
5. Always configure the FCCU reaction to NCF[26] as a short or long functional reset. Never configure it as an interrupt.
6. If RCCUs are disabled due to entry to debug mode, this fault is not triggered. If RCCU disablement occurs for another reason, this fault is triggered. See Core lockstep and RCCU disablement in debug mode for more information about RCCU disablement in debug mode.

NOTE

Functional reset is not generated by any of the fault by default (after reset).

7.12.3.2 EOUT[0:1] and FCCU_F[0:1] signals

The external signals generated by the FCCU have different names at the module level and the chip level. They are named:

- EOUT[0:1] (fcc_eout[0:1]) at the module level, such as in the dedicated FCCU chapter.
- FCCU_F[0:1] at the chip level, such as in the Signal Description chapter.

7.12.3.3 FCCU chip-specific register reset values

This table lists in alphabetical order by mnemonic the FCCU registers whose reset values are specific to this chip. (The reset values for all other FCCU registers are specified in Register descriptions.)

Register	Reset value
FCCU_CFG	Loaded from FCCU record after reset
FCCU_CFG_TO	0000_0006h
FCCU_NCF_CFG0	FFFF_FFFFh
FCCU_NCF_CFG1	FF7F_FFFFh
FCCU_NCF_CFG2	0000_07FFh
FCCU_NCF_E0	FFFF_FFFFh
FCCU_NCF_E1	0778_003Fh
FCCU_NCF_E2	0000_0720h
FCCU_NCF_TO	0000_FFFFh
FCCU_NCF_TOE0	FFFF_FFFFh
FCCU_NCF_TOE1	FF7F_FFFFh
FCCU_NCF_TOE2	0000_07FFh
FCCU_NCFS_CFG0	0000_0000h
FCCU_NCFS_CFG1	0000_0000h
FCCU_NCFS_CFG2	0000_0000h
FCCU_NCFS_CFG3	0000_0000h
FCCU_NCFS_CFG4	0000_0000h

7.12.3.4 FCCU chip-specific glitch-filter guidelines

In this chip, the FCCU glitch filter is assigned to the NCF1 channel; however, this channel is tied low instead of being connected to a pin on the boundary of the chip.

Ignore the FCCU_CTRL[FILTER_BYPASS] and FCCU_CTRL[FILTER_WIDTH] fields because they have no effect on anything.

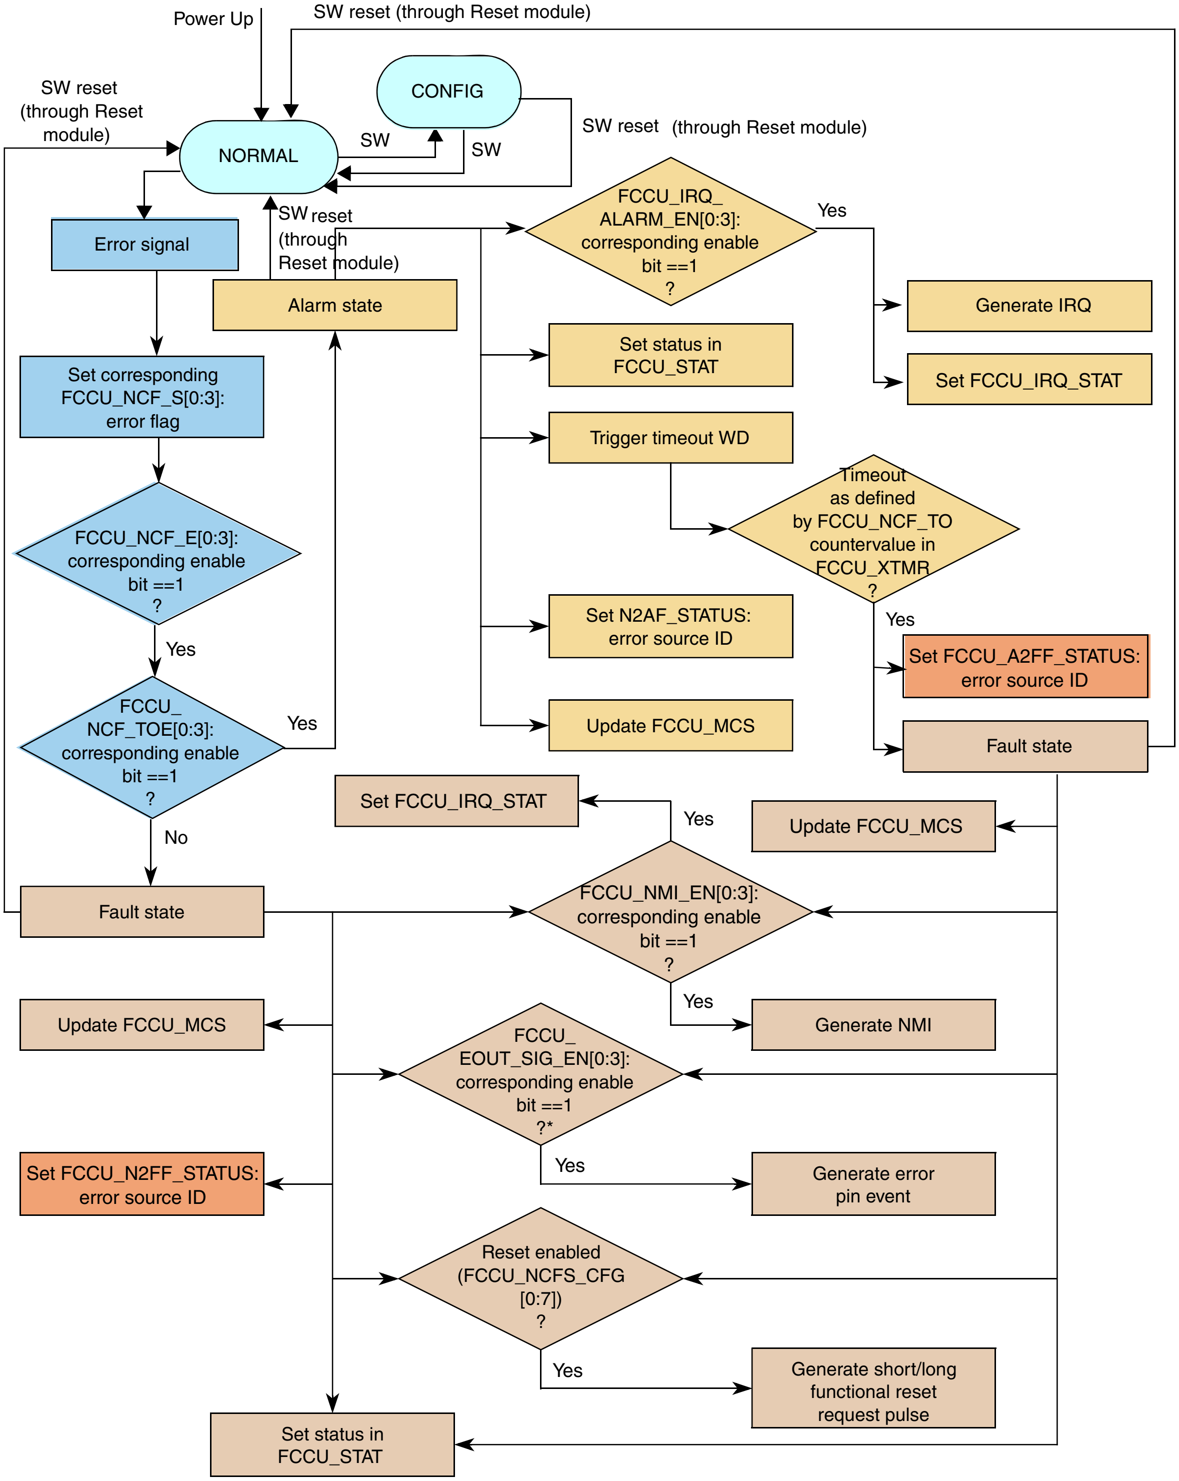
7.12.3.5 FCCU_STAT[PhysicErrorPin] reset value

The reset value of the FCCU_STAT[PhysicErrorPin] depends on the current state of the physical error pin. The value also depends on the selected protocol. See EOUT interface.

7.12.3.6 FOSU_COUNT value

The FCCU Output Supervision Unit (FOSU) has a timer whose duration is the value FOSU_COUNT. On this chip, the value is 65,535 IRCOSC clock cycles.

7.12.3.7 Error signal flow diagram



* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 7-8. Error signal flow

7.12.4 Self-Test Control Unit (STCU2) configuration

See the Self-Test Control Unit (STCU2) details.

7.12.5 Register protection (REG_PROT) configuration

7.12.5.1 List of protected registers

An appendix of this document provides a comprehensive list of protected registers on the device.

7.13 Debug

The device provides Nexus with Reduced Port Mode (RPM) and the Aurora interface (FPM) for debug access.

The Aurora interface allows the Nexus protocol information to be transmitted serially at a high rate of speed over two Aurora lanes.

See the Debug details for more information.

Table 7-34. PRN for existing Masksets

Maskset name	Part Revision Number(PRN)
1N15P	"0x3"
1N65H	"0x1"

7.14 Wakeup Unit (WKPU) configuration

The WKPU outputs an NMI source signal that triggers an interrupt connected to the NMI input of the FCCU, which generates a core wakeup signal if the chip is in stop mode or provides an NMI in all other cases.

7.14.1 Chip-specific WKPU register reset values

The following table lists WKPU register reset values that are specific to this chip.

Table 7-35. Chip-specific WKPU register reset values

Register	Reset value	Notes
NCR	0000_0000h	NDSS0 field resets to 00b

Chapter 8
Reset

8.1 Introduction

The chapter describes the global and local reset behavior of the device.

8.1.1 Global Reset

The global reset behavior refers to device reset behavior controlled by the MC_RGM which affects several modules of the device at the same time. The global reset is linked to the reset process described in Section 8.2, Global Reset Process.

8.1.2 Local Reset

The local reset behavior refers to module reset behavior controlled by the MC_RGM or dedicated modules which affects only one module at a time. Local resets are described in the module chapters.

8.2 Global Reset Process

This section describes the global reset process. Throughout this section the term *global* is omitted.

8.2.1 Overview

The global reset process is a sequence of several reset phases. Each reset phase has a specific entry condition, a specific exit condition, and a specific device reset behavior, which is different among the reset phases. The reset phases are executed in a specific order, thus building the actual global reset process. There are several modules contributing to the global reset process. All modules of the device can be affected by the global reset process.

8.2.2 Reset Process Modules

All modules which can enter, gate, or control the reset process are listed in Table 8-1 together with their type of contribution. The types of contribution are described in Table 8-2.

Table 8-1. Reset Process Modules

Module	Contribution Type		
	event	gating	control
Section 8.2.2.1, Reset Generation Module (MC_RGM)	v	v	v
Section 8.2.2.2, Power Management Controller (PMC)	v	v	v
Section 8.2.2.3, Mode Entry Module (MC_ME)	v		
Section 8.2.2.4, System Status and Configuration Module (SSCM)		v	
Section 8.2.2.5, Self-Test Control Unit (STCU)			v
Section 8.2.2.6, Fault Collection and Control Unit (FCCU)	v	v	
Section 8.2.2.7, Embedded Flash Memory (c55fmc)	v	v	
Section 8.2.2.8, JTAG Controller (JTAGC)	v		

Table 8-2. Module Contribution Type

Contribution Type	Description
event	The module may generate events which may trigger the entry into an reset state, if the event configuration in the MC_RGM allows this.
gating	The module can prevent the exit of a reset state if it has not reached a certain internal state.
control	The module controls the sequence of the reset process.

8.2.2.1 Reset Generation Module (MC_RGM)

The MC_RGM is one of three controlling modules for the reset process. The MC_RGM can receive events from other modules and starts the reset process based on the configuration for these events. The event configuration defines the reset phase at which the reset process starts. The MC_RGM also controls the reset process sequence based on the gating information it receives from the gating modules.

8.2.2.2 Power Management Controller (PMC)

The PMC provides two types of signals for the reset process control.

As long as the supply voltages are not reliable, the PMC provides signals to put the whole device into a power on reset state.

As long as the supply voltages are reliable but above or below certain operational limits, the PMC provides signals to allow the device to enter the reset process.

8.2.2.3 Mode Entry Module (MC_ME)

The MC_ME can generate events to enter the reset process. These events can be triggered only by application software.

8.2.2.4 System Status and Configuration Module (SSCM)

The SSCM is started automatically during a specific phase of the reset process. The SSCM fetches DCF records from the flash memory and distributes the read values via an internal DCF bus to the related modules. As long as the SSCM is still fetching DCF records, this specific reset phase cannot be exited.

8.2.2.5 Self-Test Control Unit (STCU)

The STCU controls the execution of the startup and shutdown self-test. Depending on its configuration, the STCU is started when PHASE3[DEST] is exited or when software triggers the self-test. The SCTU generates a functional event when the self-testing has been completed.

8.2.2.6 Fault Collection and Control Unit (FCCU)

The FCCU generates reset events and gates the reset process while it is configuring itself based on the DCF record content.

The FCCU's FOSU also generates a reset event when a fault occurs but the FCCU fails to react to that fault.

8.2.2.7 Embedded Flash Memory (c55fmc)

Failure of flash memory initialization, which generates a reset event and gates the reset process, usually results from misconfigured data for self-test or trimming.

8.2.2.8 JTAG Controller (JTAGC)

JTAGC TAP controller generates this event to allow the external debugger to reset the SoC via a JTAG command (such as JTAG EXTTEST) without using the external RESET_B pin.

8.2.3 Reset Process Sequence

This section specifies the reset process sequence. An overview of the reset process sequence appears in the following figure. When the reset process has reached the IDLE state, the device is operational.

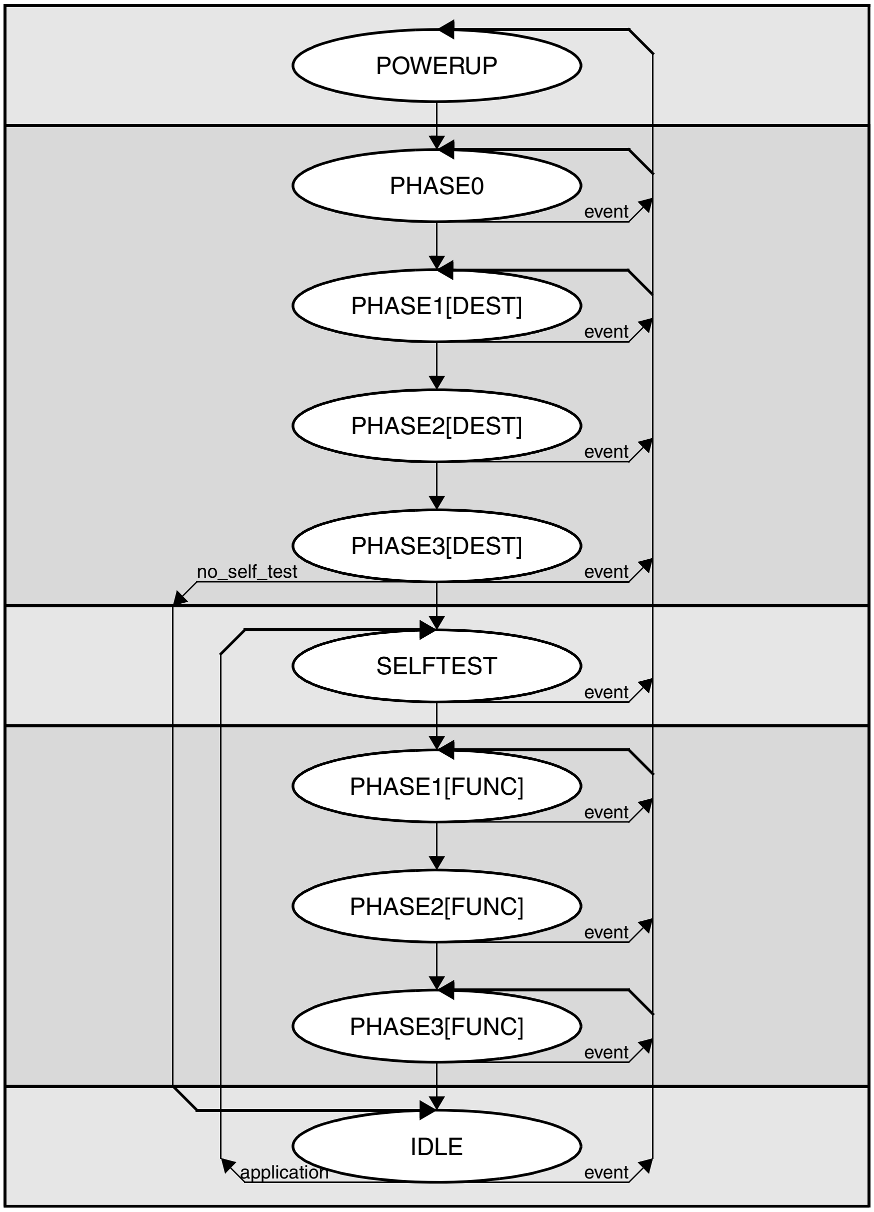


Figure 8-1. Reset Process Sequences

8.2.4 Reset Process State Transitions

This section specifies the transitions between the reset states in the reset process. For each state, the state entry, the state execution, and the state exit are described.

8.2.4.1 POWERUP

8.2.4.1.1 POWERUP State Entry

This state is entered from any state if at least one of the following events occurs:

- Power is applied to the unpowered device.
- PMC has detected a low power condition that is lower than the minimum operating voltage
- EXT_POR_B pin is driven low

8.2.4.1.2 POWERUP State Execution

During this state the PMC is waiting for stable power supply.

All output PADs are driven to known values, and all bidirectional PADs are configured as inputs.

8.2.4.1.3 POWERUP State Duration

There are no bounds on the duration of this state.

8.2.4.1.4 POWERUP State Exit

Table 8-3. POWERUP Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	(1) The EXT_POR_B pin is high and (2) the PMC module indicates all supplies are in the operational range	IRCOSC MC_RGM

8.2.4.2 PHASE0

8.2.4.2.1 PHASE0 State Entry

This state can be entered from

- all other reset states when the state exit condition is present.

8.2.4.2.2 PHASE0 State Execution

All trimming bits are reset to their default values.

All output PADs are driven to known values, and all bidirectional PADs are configured as inputs.

8.2.4.2.3 PHASE0 State Exit

Table 8-4. PHASE0 Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE1[DEST]	(1) The MC_RGM indicates that all sources of enabled destructive reset events are deasserted, and (2) the IRCOSC module indicates the generation of a stable clock, and (3) the PMC module has ***deasserted dpmc_rgm_phase0_lvd_b***.	

8.2.4.3 PHASE1[DEST]

8.2.4.3.1 PHASE1[DEST] State Entry

This state can be entered from state

- PHASE0,
- PHASE1[FUNC],
- PHASE2[FUNC],
- PHASE3[FUNC],
- IDLE.

8.2.4.3.2 PHASE1[DEST] State Execution

There are no state changes in any module; only a counter in the MC_RGM is running.

8.2.4.3.3 PHASE1[DEST] State Exit

Table 8-5. PHASE1[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	

Table continues on the next page...

Table 8-5. PHASE1[DEST] Next State Table (continued)

Next State	Condition	Process/Module Started at Exit
PHASE2[DEST]	8 IRCOSC clocks passed by after state entry.	FLASH - starts initialization sequence FCCU - enters configuration state in preparation for receiving DCF record content STCU - waits for configuration via DCF records

8.2.4.4 PHASE2[DEST]

8.2.4.4.1 PHASE2[DEST] State Entry

This state can be entered from state

- PHASE1[DEST].

8.2.4.4.2 PHASE2[DEST] State Execution

FLASH executes an initialization sequence for slow array access.

8.2.4.4.3 PHASE2[DEST] State Exit

Table 8-6. PHASE2[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE3[DEST]	The FLASH module indicates the availability of slow array access.	SSCM - starts device configuration and boot location search

8.2.4.5 PHASE3[DEST]

8.2.4.5.1 PHASE3[DEST] State Entry

This state can be entered only from state

- PHASE2[DEST].

8.2.4.5.2 PHASE3[DEST] State Execution

SSCM runs device configuration and boot location search.

The FCCU executes its configuration sequence.

The PMC adjusts its LVD and HVD levels according to the DCF record content, adjusts its output to the full voltage level, and executes its self-test.

The FLASH transitions from slow to full speed array access when full voltage has been achieved by the PMC.

8.2.4.5.3 PHASE3[DEST] State Exit

Table 8-7. PHASE3[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
SELFTEST	(1) The FLASH module indicates availability of full speed array access, and (2) the SSCM module indicates device configuration is done, and (3) the FCCU module indicates it has completed its configuration sequence, and (4) the PMC module indicates it has finished its internal self-test, and (5) the STCU module is configured to execute a startup self-test.	BIST on - FCCU - CORE - PERIPHERALS
IDLE	(1) the FLASH module indicates availability full speed array access, and (2) the SSCM module indicates device configuration is done, and (3) the FCCU module has completed its configuration sequence, and (4) the PMC module indicates it has finished its internal self-test.	CORE ALL OTHER PERIPHERALS

8.2.4.6 SELFTEST

8.2.4.6.1 SELFTEST State Entry

This state can be entered only from state

- PHASE3[DEST],
- IDLE.

8.2.4.6.2 SELFTEST State Execution

SELFTEST is running on FCCU, CORE, PERIPHERALS.

8.2.4.6.3 SELFTEST State Exit

Table 8-8. SELFTEST Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[FUNC]	STCU module indicates end of self test.	

8.2.4.7 PHASE1[FUNC]

8.2.4.7.1 PHASE1[FUNC] State Entry

This state can be entered from states

- SELFTEST
- PHASE3[FUNC]
- IDLE.

8.2.4.7.2 PHASE1[FUNC] State Execution

There are no state changes in any module; only a counter in the MC_RGM is running.

8.2.4.7.3 PHASE1[FUNC] State Duration

The duration of this state is 8 IRCOSC clock cycles.

8.2.4.7.4 PHASE1[FUNC] State Exit

Table 8-9. PHASE1[FUNC] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	When self test is enabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE1[FUNC]	The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is not an external reset. or When self test is disabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE2[FUNC]	(1) The MC_RGM indicates that all sources of enabled long functional reset events are deasserted, and (2) 8 IRCOSC clocks passed by after state entry.	FLASH - starts initialization sequence - enters configuration state in preparation for receiving DCF record content if PHASE1[FUNC] was entered on the exit of the SELFTEST state

8.2.4.8 PHASE2[FUNC]

8.2.4.8.1 PHASE2[FUNC] State Entry

This state can be entered from state

- PHASE1[FUNC].

8.2.4.8.2 PHASE2[FUNC] State Execution

FLASH executes an initialization sequence for slow array access.

8.2.4.8.3 PHASE2[FUNC] State Exit

Table 8-10. PHASE2[FUNC] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	When self test is enabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE1[FUNC]	The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is not an external reset. or When self test is disabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE3[FUNC]	The FLASH module indicates the availability of slow array access.	SSCM - starts device configuration

8.2.4.9 PHASE3[FUNC]

8.2.4.9.1 PHASE3[FUNC] State Entry

This state can be entered from states

- PHASE2[FUNC]
- IDLE.

8.2.4.9.2 PHASE3[FUNC] State Execution

SSCM runs device configuration if the state was entered from PHASE2[FUNC].

The FCCU executes its configuration sequence if PHASE3[FUNC] was entered via the SELFTEST state.

The FLASH makes the transition from slow to full speed array access.

8.2.4.9.3 PHASE3[FUNC] State Exit

Table 8-11. PHASE3[FUNC] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	When self test is enabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE1[FUNC]	The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is not an external reset. or When self test is disabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
IDLE	(1) The FLASH module indicates availability of full speed array access, and (2) the SSCM module indicates device configuration is done, and (3) the FCCU module has completed its configuration sequence, and (4) the PMC module indicates it has finished its internal self-test.	CORE ALL OTHER PERIPHERALS

8.2.4.10 IDLE

8.2.4.10.1 IDLE State Entry

The IDLE state can be entered only from states

- PHASE3[DEST]
- PHASE3[FUNC].

8.2.4.10.2 IDLE State Execution

During the IDLE state, the device is fully operational.

8.2.4.10.3 IDLE State Duration

There are no bounds on the duration of this state.

8.2.4.10.4 IDLE State Exit

The IDLE state next state table is given in the following table.

Table 8-12. IDLE Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	When self test is enabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE1[FUNC]	The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is not an external reset. or When self test is disabled: The MC_RGM has detected that the source of the enabled long functional reset event is asserted, and the source is an external reset.	
PHASE3[FUNC]	The MC_RGM has detected that the source of an enabled short functional reset event is asserted.	
SELFTEST	The application has triggered the start of the shutdown self-test.	

8.2.5 Module Status During Reset Process

The following table specifies the status of the device modules during the reset process. The status abbreviations are explained in Table 8-14.

Table 8-13. Module status during reset states

Module	POWERUP	Global Reset State								
		PHASE0	PHASE1[DEST]	PHASE2[DEST]	PHASE3[DEST]	SELFTEST	PHASE1[FUNC]	PHASE2[FUNC]	PHASE3[FUNC]	IDLE
PMC	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON
IRCOSC[1]	RST	ON	ON	ON	ON	ON	ON	ON	ON	ON
MC_RGM	RST	ON	ON	ON	ON	ON	ON	ON	ON	ON
XOSC[2]	RST	RST	RST	RST	ON	ON	ON	ON	ON	ON
FLASH	RST	RST	RST	ON	ON	ON	RST	ON	ON	ON
SSCM	RST	RST	RST	RST	ON	ON	RST	RST	ON	ON
FCCU	RST	RST	RST	ON	ON	BIST	ON	ON	ON	ON
STCU	RST	RST	RST	ON	ON	ON	ON	ON	ON	ON
CORE	RST	RST	RST	RST	RST	BIST	RST	RST	RST	ON
OTHERS	RST	RST	RST	RST	RST	BIST	RST	RST	RST	ON

1. IRCOSC registers are reset with the PHASE3 reset, but the analog portion of the IRCOSC is reset only with the POWERUP. Therefore, as the table shows, the IRCOSC is running during all phases except POWERUP.
2. XOSC registers are reset with the PHASE3 reset, but the analog portion of the XOSC is reset during the PHASE3 reset sequence (pre-self-test) only if configured in the UTEST portion of the flash memory.

Table 8-14. Module Status Glossary

Module Status	Status Description
RST	Module is held in reset by the global reset process
BIST	Module is being tested or held in a non-functional state during self-test execution as controlled by the STCU
ON	Module is functional

Chapter 9
Device Configuration Format (DCF) Records

9.1 Introduction

The system reset sequence is a complex process implementing a considerable amount of initialization before releasing reset.

Before the device can be used by an application, the application code, application specific reset values, and Device Configuration Format (DCF) records must be properly programmed into their respective flash memories. DCF records are used to configure certain registers – the DCF clients – in the device during the reset sequence. For this purpose, the System Status and Control Module (SSCM) reads the DCF records from flash and writes the configuration information to the specified DCF clients. Thus, many operational aspects of the device are properly configured before the reset signal is released and normal device operation begins.

9.2 DCF clients

DCF clients are simply designated registers in the device which receive their value from DCF records. (Some DCF clients may additionally be writable directly from the CPU, once the device has exited the reset sequence. In this case the DCF records placed in UTEST will initialize the client, i.e. defining it's reset value.)

Depending on their usage DCF clients may be equiped with a variety of safety features and modification rules.

9.2.1 Safety features of DCF clients

Depending on its role in the device, a client may be equipped with a single safety feature or a combination of safety features.

9.2.1.1 Parity

If a DCF client implements parity checking, then it will receive a parity bit additionally to it's data in the DCF record. During device operation it will continuously monitor whether the data it's stores matches the parity and report errors to the SSCM.

9.2.1.2 Triple voting

DCF clients that use the triple voting have three copies of the register. The SSCM will write to all three registers in a single write cycle. During device operation the DCF client continuously monitors whether all three copies match and reports errors to the SSCM. The device will use the majority result, so single errors will not affect device operation.

9.2.1.3 Spread triple voting

DCF clients that use spread triple voting have three copies of the register which are individually addressed and where the data is stored in three different formats. The SSCM will fetch these records independently. During device operation the DCF client continuously monitors whether all three copies can be resolved from the stored format to the the value and reports errors to the SSCM. The device will use the majority result, so single errors will not affect device operation.

9.2.1.4 Second write check

This feature is used by DCF clients which receive their records twice - e.g. once before and once after BIST for clients which retain their value during self test. They will monitor whether the second write matches the first and report deviations to the SSCM.

9.2.2 DCF client modification rules

Depending on its role in the device a client may implement one or a combination of modification rules. If a modification rule is in effect, the order in which DCF records are placed in the record list may be important.

9.2.2.1 Write Once

A DCF client using the Write Once rule can only be written with a single DCF record. Records appended later in the list will be ignored and not change the value of the client.

9.2.2.2 Write 0 only

A bit in a DCF client can only be written from a 1 to a 0. So, if an earlier DCF record has set a bit to 0, then an attempt by a later record to set this bit to a 1 will be ignored.

9.2.2.3 Write 1 only

A bit in a DCF client can only be written from a 0 to a 1. So, if an earlier DCF record has set a bit to 1, then an attempt by a later record to set this bit to a 0 will be ignored.

9.3 DCF records

An individual DCF record consists of information to locate the corresponding DCF client internal to the device (control word) and the data to be written to that client (data word).

DCF records appear as contiguous series of entries programmed at a specific address within flash memory. The following structure must be present:

- The first DCF record must be a start record. This record must be placed at the beginning of a DCF area in flash memory to indicate to the device that the following records must be processed.
- DCF records containing configuration data must immediately follow the start record with no blank records between-an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed. This allows one to program the records in several sessions, each time appending new records at the end of the list.
- The end of the configuration records are indicated by the presence of a stop record; indicated by the stop bit being set. Normally, the stop bit is never set in a valid UTEST DCF record programmed during production, since this would prevent appending additional UTEST records. The flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location. Therefore, that location's contents will be 0xFFFF_FFFF. Thus, the stop bit location in this unprogrammed flash memory location will be a logic 1, signifying that this is the last DCF record and it is not to be acted upon.

For a detailed discussion of the basic DCF record format, its fields, and specific records (start, stop) refer to the corresponding chapter in the documentation of the System Status and Control Module (SSCM).

9.4 DCF clients available in the SOC

This section describes user-visible DCF clients in the device. These clients can be controlled by programming DCF records in UTEST. The default values given are those which are active if there are no records for these clients in UTEST.

Table 9-1. Clients which can be set by the user.

9.4.1 Security and serial boot mode records

For a description for the flash memory backdoor password, serial boot mode, and security records, see the SSCM details in Security and Serial access security.

9.4.2 OTP records

The description of the OTP records is in the Flash OTP Control details.

9.4.3 FCCU record

The FCCU record allows you to define the initial value for the FCCU_CFG register. The register holds this initial value after the device exits the reset sequence. See Figure 9-1. For a description of the register, see the dedicated FCCU chapter.

As a client with high importance for the safety concept, the FCCU DCF client uses the spread triple voting feature. This feature means that three records must be written to set the values for the client.

The meaning of the data bits is not the same for all records. The first record uses the standard format, the second inverts the values of the first (see Figure 9-2), and the third shift-rotates the values to the left (see Figure 9-3).

9.4.5 STCU configuration records

The STCU provides a large number of configuration records. The STCU chapter provides details.

Chapter 10
Device Security

10.1 Device Security

Device security, which is implemented by the SSCM, focuses on preventing unauthorized access to the flash memory contents.

The following features are available:

- 64-bit password protection
- Challenge timeout to protect against brute force attacks
- Swallowed key feature
- Voltage-attack protection
- Public serial boot mode to allow limited device diagnostics without giving access to the Flash
- Private serial boot mode for application code update
- JTAG unsecure feature to allow debugging of secured devices for authorized developers

Chapter 11
Debug

11.1 Introduction

The chapter discusses the device specific information for the debug modules. This device implements both, a Nexus trace auxiliary port with MDO/MSEO pins and a Nexus Aurora interface. The Aurora interface allows the Nexus protocol information to be transmitted serially at a high rate of speed over two Aurora lanes. The Aurora protocol handles the encoding of the data and striping the information across the Aurora lanes available on the device. The device starts up in JTAG mode.

The Event Out ($\overline{\text{EVTO}}$) signal is connected to the external PAD[90] device pin and the Event In (EVTI_IN) signal is connected to the external PAD[91] device pin.

NOTE

It should be expected that during a destructive reset event, the entire device is reset including debug modules and the debugger loses connectivity with the chip. Whenever the device is under debug and gets a long functional reset, it will lose connection with the debugger. During software development if a reset cycle is necessary without disconnecting the debugger, a short functional reset can be used.

11.2 e200z4 core debug support

Internal debug support in the e200z4 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes.

For details, see e200z4 Core Debug Support.

11.3 Core lockstep and RCCU disablement in debug mode

In debug mode, the RCCUs are disabled, and the cores do not operate in Lockstep mode.

The actual enabled/disabled state of the RCCUs (including any automatic disablement by debug) can be read by software in the RCCU Status (RCCU_STAT) register.

Table 11-1. RCCU Status register details

Address	Register name	Width (in bits)	Access	Reset value
FFC0_C004h	RCCU_STAT	32	R	0000_0000h

The read-only RCCU Status register holds the RCCU Status Flag (RSF) that indicates RCCU enablement/disablement.

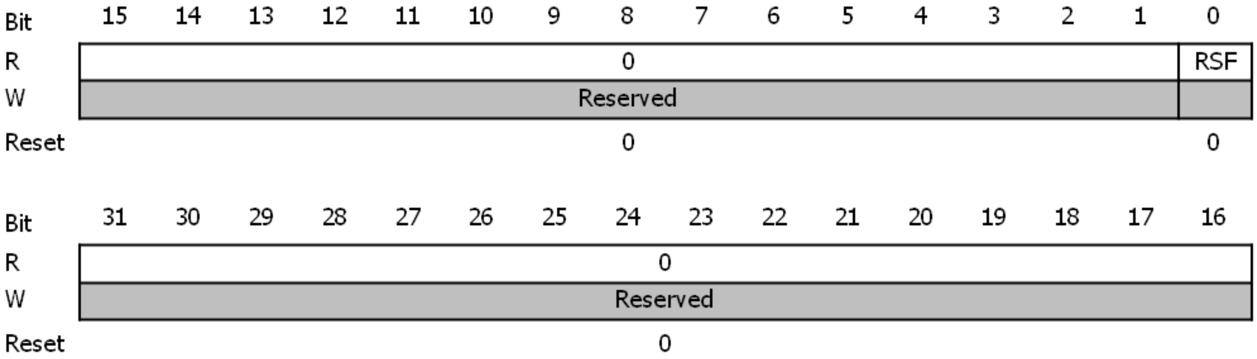

Table 11-2. RCCU_STAT field descriptions

Field	Description
0 RSF	RCCU active Status Flag 0 RCCUs are disabled. Cores are not in Lockstep mode. 1 RCCUs are enabled. Cores are in Lockstep mode.
1-31 Reserved	This read-only field is reserved and always has the value 0.

11.4 Run control and memory access

Run control is any operation required to control the device operation. Run control includes starting and stopping execution of code by the processor, as well as access to memory while the device is stopped to download code.

The JTAG interface supports both boundary scan and debug modes. It is based on the IEEE1149.1-2001 standard. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface.

11.5 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG controller.

For details, see the JTAG Controller (JTAGC) chapter.

11.5.1 JTAGC ACCESS_AUX block instructions

The ACCESS_AUX instructions are described in this table.

Table 11-3. ACCESS_AUX 5-bit JTAG instructions

Instruction	Code[4:0]	Instruction Summary
ACCESS_AUX_x	10000–11110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
ACCESS_AUX_NPC	10000	Enables access to the NPC TAP controller
Reserved	10001	Reserved
Reserved	10010	Reserved
Reserved	10011	Reserved
Reserved	10100	Reserved
Reserved	10101	Reserved
Reserved	10110	Reserved
ACCESS_AUX_NXMC_0	10111	Enables access to the Nexus XBAR Multimaster Client 0 TAP controller
ACCESS_AUX_NXMC_1	11000	Enables access to the Nexus XBAR Multimaster Client 1 TAP controller
Reserved	11001	Reserved
ACCESS_AUX_LSM	11010	Enables access to multiple cores in parallel when in lock step mode (LSM)
Reserved	11011	Reserved
Reserved	11100	Reserved
Reserved	11101	Reserved
ACCESS_AUX_NAL	11110	Enables access to NAL

11.5.2 TEST_CTRL register

The following register details elaborate on the general description in TEST_CTRL Register of the dedicated JTAGC chapter.

TEST_CTRL

LSB=0	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BSR_HYS	BSR_SRE[1:0]		BSR_PUS	BSR_PUE	BSR_PAD_CTRL_EN	(R)0[1]	(R)0[1]	(R)0[1]	NEX_RDY_PORT_EN	(R)1	(R)0[1]	(R)1[1]	(R)1[1]	(R)1[1]	(R)0[1]	(R)1[1]
Reset	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1	0	1

1. This bit is reserved. The defined value ensures future compatibility.

Table 11-5. TEST_CTRL register field descriptions

Field	Description
BSR_HYS	BSR Input Hysteresis Control Enables input hysteresis for the associated pin 0 Disabled 1 Enabled
BSR_SRE[1:0]	BSR Slew Rate Control Controls the slew rate of the output driver 00 Half drive strength with slew rate control 01 Full drive strength with slew rate control 10 Half drive strength without slew rate control 11 Full drive strength without slew rate control
BSR_PUS	BSR Pads Pull Select Selects pull-up or pull-down 0 pull-down selected 1 pull-up selected
BSR_PUE	BSR Pads Pull Enable Enables active pull-up/down 0 pull disabled 1 pull enabled
BSR_PAD_CTRL_EN	Boundary Scan Mode Pad Control Enable Enables the pad controls for all BSR pads when the JTAG EXTEST or CLAMP instruction is active. Control occurs via the PTI module. 0 BSR pad control disabled

Table continues on the next page...

Table 11-5. TEST_CTRL register field descriptions (continued)

Field	Description
	1 BSR pad control enabled
NEX_RDY_PORT_EN	RDY_B Enable Enables RDY_B functionality for corresponding GPIO pin. Setting this bit overrides the SIUL2 output muxing configuration for the corresponding pad. 0 Disables RDY_B functionality (output mux for the pad is controlled by SIUL2) 1 Enables RDY_B functionality (output mux for the pad is controlled by JTAGC)

11.5.3 Device identification register reset values

The reset value of the Device identification register (JTAG ID) Register depends on the chip version:

- Maskset N15P : 29B4501Dh
- Maskset 1N65H : 19B4501Dh
- Maskset 0N65H : 09B4501Dh

11.6 Nexus Port Controller (NPC)

11.6.1 Chip-specific NPC information

This section presents device-specific parameterization, customization, and feature availability information not specifically referenced in the remainder of this chapter.

11.6.1.1 Parameter values

The parameter values for this device are shown in the following table.

Table 11-6. Device parameter values

Parameter	Value
Number of MDO pins available (Reduced port mode)	4
Part identification number (PIN)	345h
Manufacturer identity code (MIC)	00Eh
Design center code (DC)	26h

11.6.1.2 DID register reset and parameter values

The reset value of the Nexus Device ID (DID) Register depends on the chip version:

- Maskset 1N65H: 19B4501Dh
- Maskset 0N65H: 09B4501Dh
- Maskset N15P: 29B4501Dh

The PRN, PIN, and DC parameters define the chip-specific values of correspondingly named fields in the DID register. The following table provides the values of those DID fields and of the register's MIC field.

Table 11-7. Values of PRN, DC, PIN, and MIC fields of DID register

DID field	Device-specific value
PRN	1h[1]
DC	26h
PIN	345h
MIC	00Eh

[1] For maskset 0N65H, PRN is 0h.

11.6.1.3 ACR field values

The LVDS_RXOPT and LVDS_TXOPT fields of the Aurora Configuration Register (ACR) function as controls for LVDS pads. For these fields, the following table identifies the bits actually used on the device and the meaning of their settings.

NOTE

> Bits that are not listed are reserved.

Table 11-8. Settings for LVDS_RXOPT and LVDS_TXOPT fields of ACR

Field bit	Device-specific setting descriptions
LVDS_RXOPT1	Default value is 0. When set to 1, increases RX current by 20%.
LVDS_RXOPT0	Default value is 0. When set to 1, decreases RX current by 20%.
LVDS_TXOPT7	Default value is 0. When set to 1, decreases internal bias current by 50%.
LVDS_TXOPT6	Default value is 0. When set to 1, increases internal bias current by 50%.
LVDS_TXOPT[4:3]	For each bit: Default value is 0. When set to 1, decreases output current by 12.5%.
LVDS_TXOPT[2:1]	For each bit: Default value is 0. When set to 1, increases output current by 12.5%.

11.6.1.4 Unavailable features

- MCKO division factor of 3 is not supported on this device. Therefore, the setting PCR[MCKO_DIV] = 2 is not available
- Nexus DDR mode is not available on this device
- PSTAT mode is not available on this device

The following bits in the Port Configuration Register should always be written as zeros. These features are not available in the device:

- DDR_EN
- NEXCFG
- PSTAT_EN
- LP2_SYN

11.6.2 Block diagram

The following figure is a block diagram of the Nexus Port Controller (NPC) block.

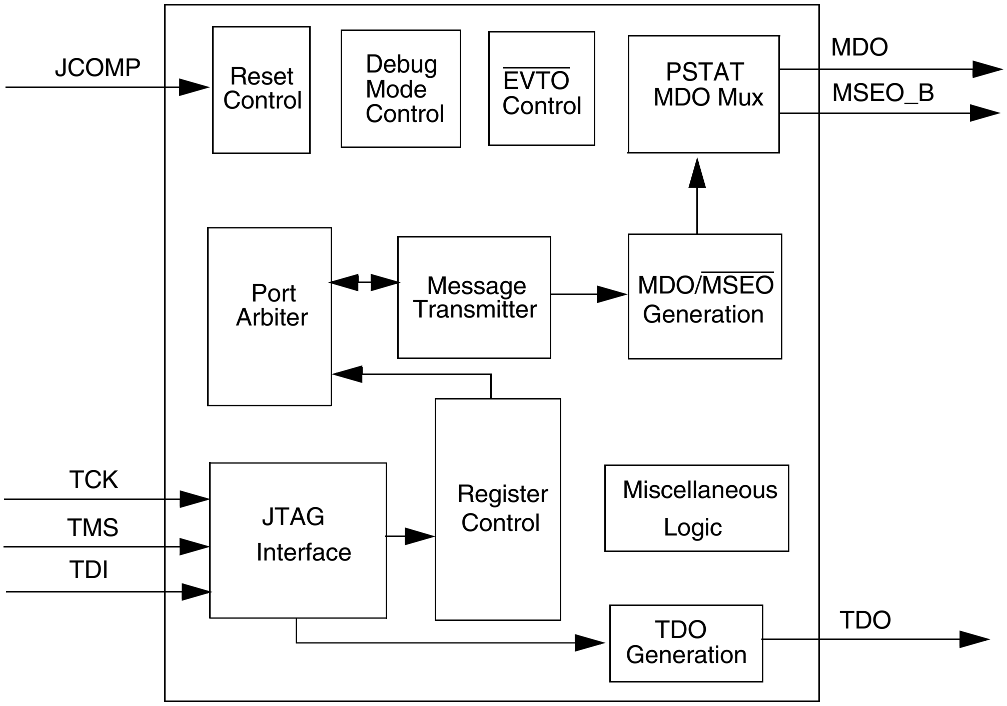

Figure 11-1. Nexus Port Controller Block Diagram

11.6.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001. The blocks share input and output ports that interface with the development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

11.6.2.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Auxiliary Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of EVTO
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus blocks based on JCOMP input, censorship status, and power-on reset status
- System clock locked status indication via MDO[0] following power-on reset
- Provides Nexus support for censorship mode
- Controls arbitration for ownership of the Nexus Aurora Link (NAL) in Aurora Link mode
- $\overline{\text{RDY}}$ pin support to increase the transfer rate of the IEEE 1149.1 port for large data read requests
- Low-power debug handshaking: see NPC Handshake

NOTE

MCKO may be gated one clock period early when MCKO's frequency is programmed as divide by 8 (MCKO_DIV= b111) and the MCKO gating function is enabled (MCKO_GT=1). In this case, the last MCKO received by the tool prior to the gating will correspond to the END_MESSAGE state. The tool will not receive an MCKO to indicate the transition to the IDLE state even though the NPC will transition to the IDLE state internally. Upon re-enabling of MCKO the first MCKO edge will drive the Message Start/End Output (MSEO=11) and move the tool's state to IDLE. Expect to receive the MCKO edge corresponding to the IDLE state upon re-enabling of MCKO after MCKO has been gated.

11.6.2.3 Modes of operation

The NPC block uses the JCOMP input, the censorship status, and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings. All available modes can be seen in Table 11-12.

11.6.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, JCOMP is not set for Nexus access, the device enters censored mode, or the JTAG Test Access Port (TAP) controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The auxiliary output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset, censored mode or JCOMP not set for NPC operation only)
- Registers default back to their reset values

11.6.2.3.2 Disabled-Port mode

In disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through $\overline{\text{EVTO}}$.

11.6.2.3.3 Aurora Link mode (High Speed Debug mode)

In Aurora Link mode, trace data is transmitted through the Nexus Aurora Link (NAL) instead of the auxiliary port. For SoCs that support a Nexus Aurora Link, the FPM bit in the PCR functions as the Aurora Link enable, leaving reduced port mode (RPM) as the only available mode for data transmission via the auxiliary port. Aurora Link Mode is enabled by setting the MCKO_EN and FPM bits and selecting a non-zero value for the ALC_NUM_LN bits in the PCR. The MCKO_DIV value should be set to select a clock frequency equal to the system clock frequency (MCKO_DIV = 000).

11.6.2.3.4 Reduced-Port mode (Auxiliary Interface Debug mode)

Reduced-port mode (RPM) is entered by asserting the MCKO_EN bit and deasserting the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific. Nexus Aurora Link is not available.

11.6.2.3.5 Censored mode

When the device is in censored mode, reading the contents of internal flash externally is not allowed. To prevent Nexus modules from violating censorship, the NPC is held in reset when in censored mode, asynchronously holding all other Nexus modules in reset as well. This prevents Nexus read/write to memory mapped resources and the transmission of Nexus trace messages.

11.6.3 External signal description

11.6.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The following table outlines NPC pin definitions.

Table 11-9. NPC Signal Properties

Name	Port	Function	Reset State	Pull
$\overline{\text{EVTO}}$	Auxiliary	Event Out pin	0b1	-
$\overline{\text{EVTI\_IN}}$	Auxiliary	Event In pin	-	-
JCOMP	JTAG	JTAG Compliancy and TAP Sharing Control	-	Down
MDO[3:0]	Auxiliary	Message Data Out pins	0	-
$\overline{\text{MSEO}}$[1:0]	Auxiliary	Message Start/End Out pins	0b11	-
TCK	JTAG	Test Clock Input	-	Up
TDI	JTAG	Test Data Input	-	Up

Table continues on the next page...

Table 11-9. NPC Signal Properties (continued)

Name	Port	Function	Reset State	Pull
TDO	JTAG	Test Data Output	High Z	-
TMS	JTAG	Test Mode Select Input	-	Up
$\overline{\text{RDY}}$	JTAG	Data ready for transfer to/from Nexus Recommended Registers (NRRs; see also the IEEE-ISTO 5001-2003 standard)	-	-

11.6.3.2 Detailed signal descriptions

This section describes each of the signals listed in Table 11-9 in more detail. The JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

11.6.3.2.1 $\overline{\text{EVTO}}$- Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

11.6.3.2.2 JCOMP - JTAG Compliancy

The JCOMP signal provides the ability to share the TAP. The NPC TAP controller is enabled when JCOMP is set to the NPC enable encoding; otherwise the NPC TAP controller remains in reset.

11.6.3.2.3 MDO - Message Data Out

Message Data Out (MDO) are output pins used for uploading Ownership Trace Messaging (OTM), Branch Trace Messaging (BTM), Data Trace Messaging (DTM) and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

11.6.3.2.4 MSEO_B - Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample $\overline{\text{MSEO}}$ on the rising edge of MCKO.

11.6.3.2.5 TCK - Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

The JTAG Clock (TCK) typically operates at a frequency well below the system clock frequency, as specified in the electrical data sheets. In some cases, however, such as low power mode, the system clock frequency may be lowered significantly from the normal operating range. If the system clock frequency is reduced below the frequency of TCK it will no longer be possible to communicate with the Nexus Port Controller Port Configuration Register (PCR). Therefore, if the tool needs to update the PCR Low Power Debug Enable (PCR[LP_DBG]) or Low Power Synchronization bits (PCR[LP1_SYN] and PCR[LP2_SYN]), the clock frequency must be lowered.

Ensure that the frequency of TCK does not exceed the system clock frequency during normal operation and during low power operation. For usage of the NPC/Nexus/NXSS subsystem, TCK clock frequency needs to be smaller than SYSCLK/2.

11.6.3.2.6 TDI - Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

11.6.3.2.7 TDO - Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

11.6.3.2.8 TMS - Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

11.6.3.2.9 $\overline{\text{RDY}}$ - Data ready for transfer

The $\overline{\text{RDY}}$ pin exists to increase the transfer rate of the IEEE 1149.1 port. It is used to signal when data are ready to be transferred to and from the NRRs (see also IEEE-ISTO 5001-2003). This may eliminate the need to poll NRRs for status information for synchronization purposes. This capability becomes especially important when performing read/write access transfers to different speed target memories.

The $\overline{\text{RDY}}$ pin asserts (asynchronously) a logic low whenever the read/write access transfer has completed without error and then deasserts when the IEEE 1149.1 state machine has reached the CAPTURE_DR state.

The $\overline{\text{RDY}}$ pin is controlled by the TEST_CTRL register in the JTAGC module. See the JTAG Controller (JTAGC) chapter.

11.6.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

The following table shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers. Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions in Nexus Port Controller (NPC) chapter for more details.

Table 11-10. NPC Registers

Index	Register
0	Device ID Register (DID)
126	Aurora Configuration Register (ACR)
127	Port Configuration Register (PCR)

11.6.4.1 Register descriptions

11.6.4.1.1 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

11.6.4.1.2 Instruction Register

The NPC block uses a 4-bit instruction register as shown in the following table. The instruction register is accessed via the SELECT_IR_SCAN path of the TAP controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE; see also Table 11-21) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

NOTE

For details, see Figure 11-5.

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3
R	Previous Instruction Opcode			
W	Instruction Opcode			
Reset:	BYPASS Instruction Opcode (0xF)			

11.6.4.1.3 Nexus Device ID Register (DID)

The device identification register allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the auxiliary output port.

11.6.4.1.4 Aurora Configuration Register (ACR)

The ACR is used to configure the RXOPT and TXOPT settings of the LVDS receive and transmit pads.

11.6.4.1.5 Port Configuration Register (PCR)

The PCR is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

The PCR register may be rewritten by the debug tool subsequent to the enabling of the NPC for low power debug support. In this case, the debug tool may set and clear the LP_DBG and LPn_SYN bits, but must preserve the original state of the remaining bits in the register. For details, see NPC Handshake.

NOTE

> The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

11.6.5 Functional Description

11.6.5.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the auxiliary port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

For Nexus Aurora Link, asserting the MCKO_EN and FPM bits and setting the NUM_ALC_LN bits to a non-zero value enables NAL data transmission. Transmission of data via the auxiliary port is enabled only by selecting the RPM configuration in this case.

The following table describes the NPC reset configuration options.

Table 11-12. NPC Reset Configuration Options

JCOMP Equal to 1?	MCKO_EN bit of the Port Configuration Register	NUM_ALC_LN bits of the Port Configuration Register > 0?	FPM bit of the Port Configuration Register	Configuration
no	X	X	X	Reset
yes	0	X	X	Disabled
yes	1	yes	1	Aurora Link Mode
yes	1	X	0	Reduced-Port Mode

NOTE

> If the device is censored, the NPC is held in reset, asynchronously holding all other Nexus modules in reset as well

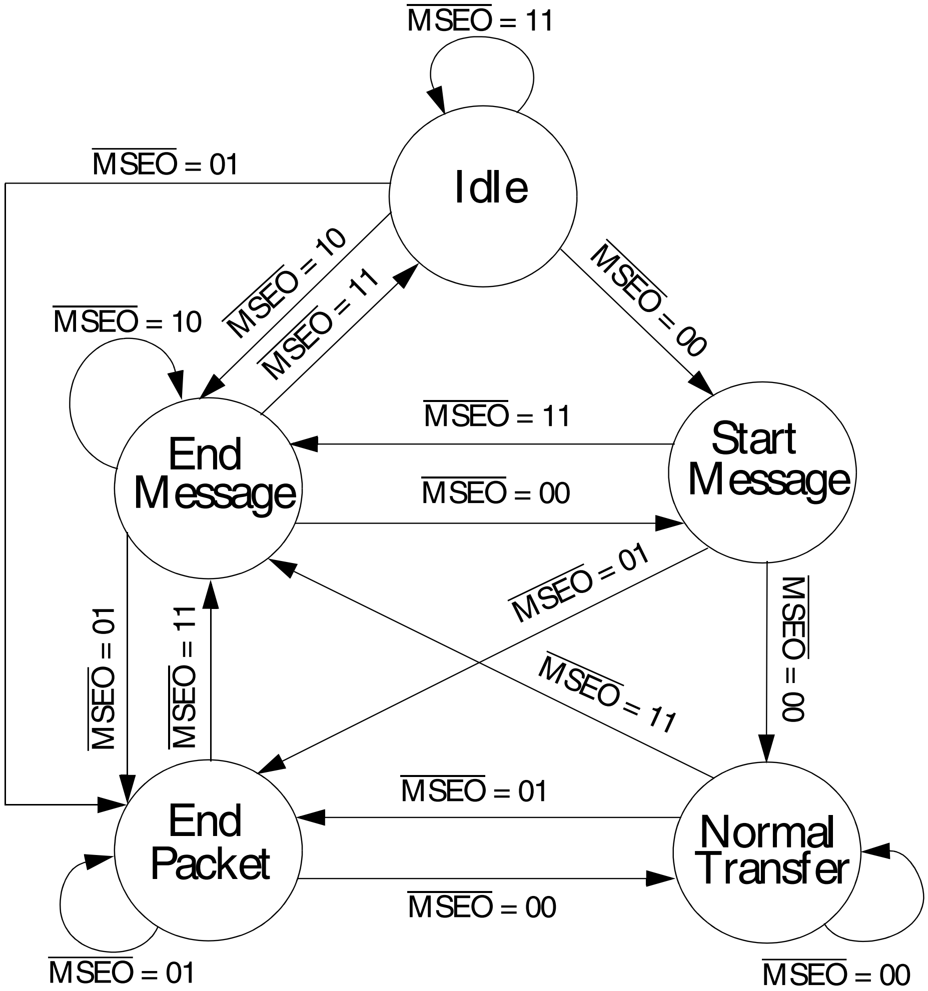
11.6.5.2 Auxiliary output port

The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

11.6.5.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the $\overline{\text{MSEO}}$ functions. The $\overline{\text{MSEO}}$ pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and $\overline{\text{MSEO}}$ are sampled on the rising edge of MCKO.

The following figure illustrates the state diagram for $\overline{\text{MSEO}}$ transfers. All transitions not included in the figure are reserved, and must not be used.



$\overline{\text{MSEO}}$ = 11
Idle
$\overline{\text{MSEO}}$ = 01
$\overline{\text{MSEO}}$ = 10
$\overline{\text{MSEO}}$ = 11
$\overline{\text{MSEO}}$ = 00
$\overline{\text{MSEO}}$ = 10
End Message
$\overline{\text{MSEO}}$ = 11
Start Message
$\overline{\text{MSEO}}$ = 00
$\overline{\text{MSEO}}$ = 01
$\overline{\text{MSEO}}$ = 11
$\overline{\text{MSEO}}$ = 01
$\overline{\text{MSEO}}$ = 11
$\overline{\text{MSEO}}$ = 00
End Packet
$\overline{\text{MSEO}}$ = 01
Normal Transfer
$\overline{\text{MSEO}}$ = 00
$\overline{\text{MSEO}}$ = 01
$\overline{\text{MSEO}}$ = 00

Figure 11-2. $\overline{\text{MSEO}}$ bit transfers (for 2-bit $\overline{\text{MSEO}}$)

11.6.5.2.2 Output Messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register and the port replacement output message on the MDO pins. The device ID message can also be sent out serially through TDO.

The following table describes the device ID and port replacement output messages that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

Table 11-13. NPC Output Messages

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Device ID Message	6	6	fixed	TCODE	Value = 1

Table continues on the next page...

Table 11-13. NPC Output Messages (continued)

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
	32	32	fixed	ID	DID register contents
Aurora Link Overrun Error Message	6	6	fixed	TCODE	Value = 8
	4	4	fixed	SRC	Nexus Aurora Link SRC value (SRC=0xF).
	5	5	fixed	ECODE	Value = 01000. Error code indicating overrun of NAL FIFO.

The following table shows the various message formats that the pin interface formatter must encounter. Note that for variable-length fields, the transmitted size of the field is determined from the range of the least significant bit to the most significant non-zero-valued bit (i.e. most significant zero-valued bits are not transmitted).

Table 11-14. Message Field Sizes

Message	TCODE	Field #1	Field #2	Field #3	Field #4	Field #5	Min. Size[1] (bits)	Max Size[2] (bits)
Device ID Message	1	Fixed = 32	NA	NA	NA	NA	38	38
Aurora Link Overrun Error Message	8	Fixed=4	Fixed=5	N/A	N/A	N/A	15	15

[1] Minimum information size. The actual number of bits transmitted depends on the number of MDO pins.

[2] Maximum information size. The actual number of bits transmitted depends on the number of MDO pins.

The double edges in the preceding table indicate the starts and ends of messages. Fields without shaded areas between them are grouped into super-fields and can be transmitted together without end-of-packet indications between them.

11.6.5.2.3 Rules of Message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.

- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. Figure 17 shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

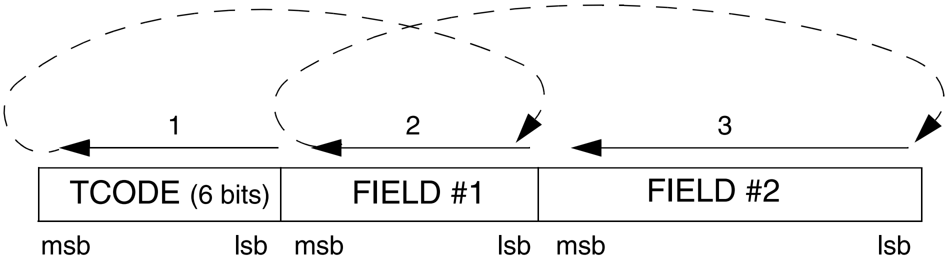


Figure 11-3. Transmission sequence of messages

11.6.5.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 TAP for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller. The value of the JCOMP input controls ownership of the port between Nexus and non-Nexus blocks sharing the TAP.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in Figure 11-5. The Nexus controller state machine is defined by the IEEE-ISTO 5001-2003 standard. It is shown in Figure 11-6.

The instructions implemented by the NPC TAP controller are listed in the following table. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4-bits.

Table 11-15. Implemented Instructions

Instruction Name	Private/Public	Opcode	Description
NEXUS-ENABLE	public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

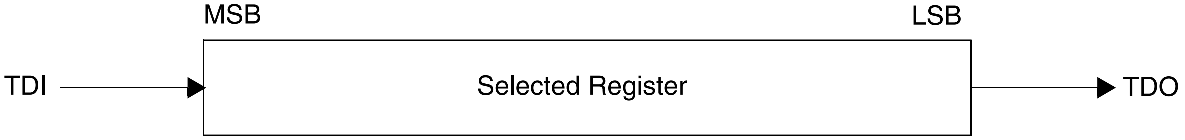

Figure 11-4. Shifting data into register

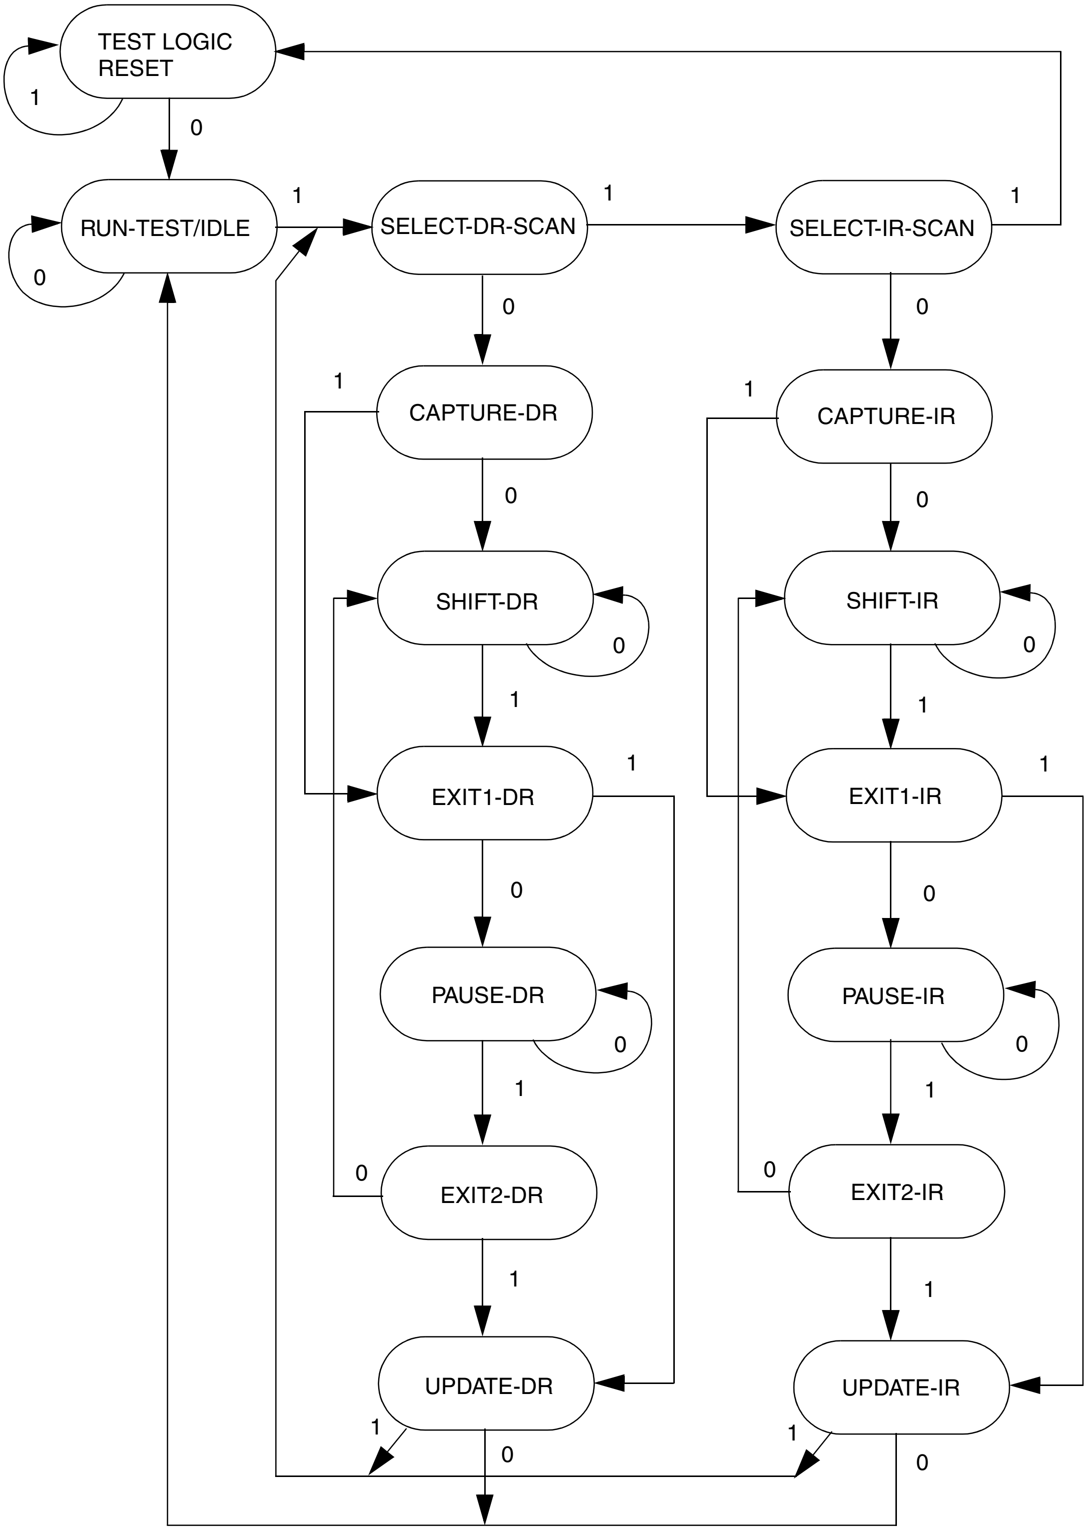
11.6.5.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal, entry into censored mode, or setting JCOMP to a value other than the NPC enable encoding resets the NPC TAP controller. When not in power-on reset or censored mode, the NPC TAP controller is enabled by driving JCOMP with the NPC enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.



NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 11-5. IEEE 1149.1-2001 TAP Controller state machine

11.6.5.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the auxiliary output port or shifted out serially by accessing the Nexus Device ID register through the TAP. Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled. Transmission of the device identification message serially via TDO is achieved by performing a read of the register contents as described in "Selecting a Nexus Client Register" section .

11.6.5.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 20 transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. Following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

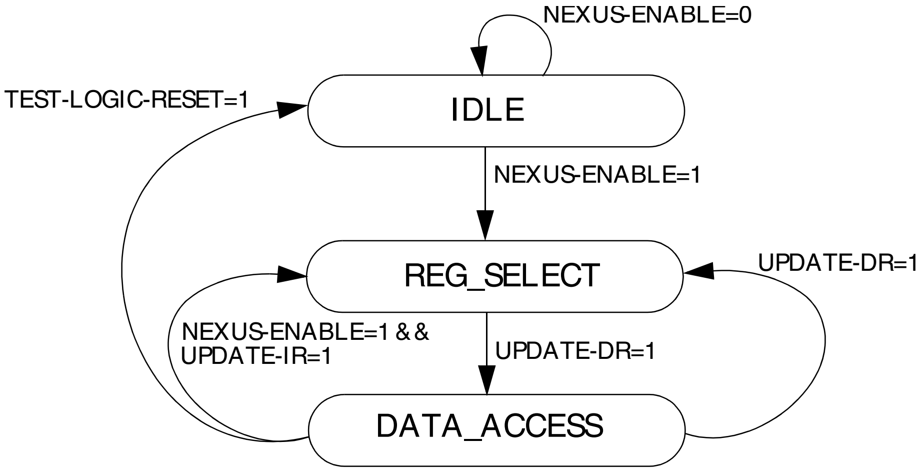


Figure 11-6. NEXUS controller state machine

Table 11-16. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction

Table continues on the next page...

Table 11-16. Loading NEXUS-ENABLE instruction (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

11.6.5.3.4 Selecting a Nexus Client register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in Figure 21. The read/write control bit is set to 1 for writes and 0 for reads.

Table 11-17. IEEE 1149.1 Controller Command Input

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE

1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

Following table illustrates a sequence which writes a 32-bit value to a register

Table 11-18. Write to a 32-Bit Nexus Client register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

11.6.5.4 Nexus JTAG port sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

11.6.5.5 MCKO

MCKO is an output clock to the development tools used for the timing of MSEO and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1.

11.6.5.6 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

11.6.5.7 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus blocks. If JCOMP is negated, an internal reset is asserted, indicating that all Nexus modules should be held in reset. Internal Nexus reset is also asserted when the device is in censored mode.

11.6.5.8 System clock locked indication

Following a power-on reset, MDO[0] can be monitored to provide the lock status of the system clock. MDO[0] is driven to a logic 1 until the system clock achieves lock after exiting power-on reset. Once the system clock is locked, MDO[0] is negated and tools may begin Nexus configuration. Loss of lock conditions that occur subsequent to the exit of power-on reset and the initial lock of the system clock do not cause a Nexus reset, and therefore do not result in MDO[0] driven high.

11.6.5.9 Data Transmission via Nexus Aurora Link

As an alternative to data transmission on the Nexus auxiliary port, the NPC also supports data transmission over a high-speed serial Nexus Aurora Link (NAL). The NPC's role in Aurora Link data transmission is to route trace data to the NAL while continuing to manage arbitration between Nexus clients for the right to transmit data. In addition, the NPC monitors the NAL transmit queue and will halt further data transmission from Nexus clients if the queue is in danger of an overrun condition. In the event of an overrun condition, the NPC transmits a standard Nexus error message.

Once the PCR is configured for Aurora Link Mode (MCKO_EN bit set, FPM bit set, ALC_NUM_LN set to non-zero value), the NPC waits for the NAL to acknowledge it is ready before starting data transmission. The NPC IDCODE message is the first message transmitted after Aurora Link mode is successfully configured and the NAL acknowledges it is ready to receive data. All data transmitted in Aurora Link mode is transmitted in frames, with each frame consisting of 8192 bytes of data. The first beat of each frame is accompanied by the assertion of the start of frame control signal, and the last beat of each frame is accompanied by the assertion of the end of frame control signal. Each beat of valid NAL data from the NPC is also accompanied by the assertion of the NAL data valid message signal.

Data received by the NAL is held in a FIFO until it can be sent out on the Aurora Link. The NPC keeps track of the NAL FIFO fill level. To help prevent an overrun of the NAL FIFO, the NPC holds off further grants to all clients if the NAL FIFO is filled above the watermark level. In the event that the NAL FIFO is overrun with data, the NPC transmits its FIFO overrun error message shown in Table 11-13.

11.6.6 Initialization/Application Information

11.6.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001 standard for more detail.

11.7 NPC Handshake

11.7.1 Overview

The NPC_HNDSHK manages the low-power mode debug handshaking between the Nexus Port Controller (NPC) and the mode entry module (MC_ME).

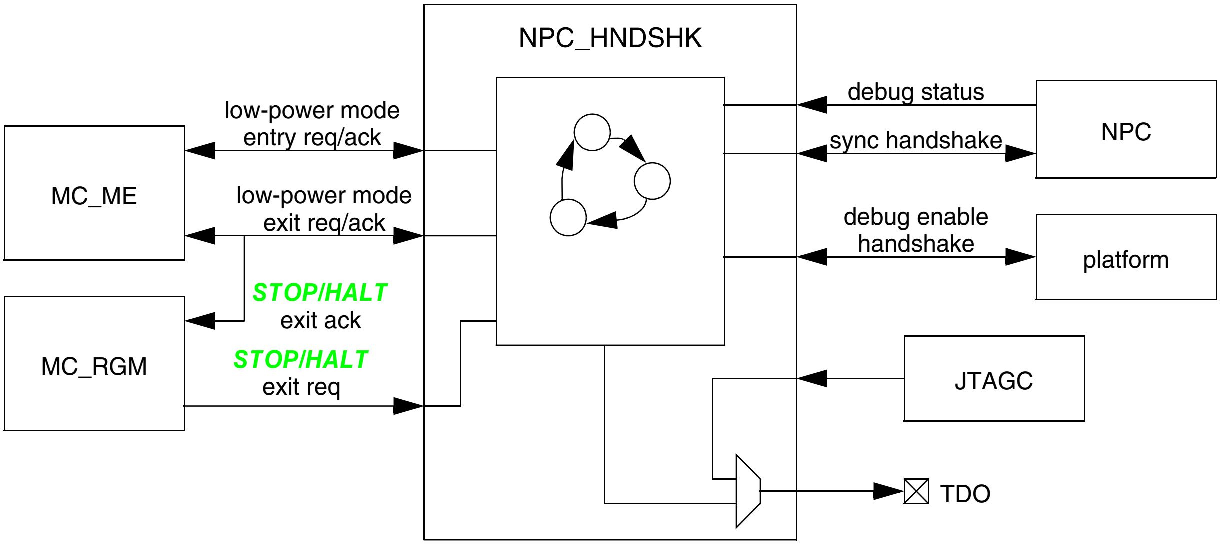

Figure 11-7. NPC_HNDSHK block diagram

11.7.2 Features

The NPC_HNDSHK supports:

- setting and clearing of the NPC PCR sync bit on low-power mode entry and exit
- putting the core into debug mode on low-power mode exit
- generating a falling edge on the JTAG TDO pad on low-power mode exit

11.7.3 Functional Description

11.7.3.1 Operation

The NPC_HNDSHK implements the state machine shown in following figure. The states are described in the following table.

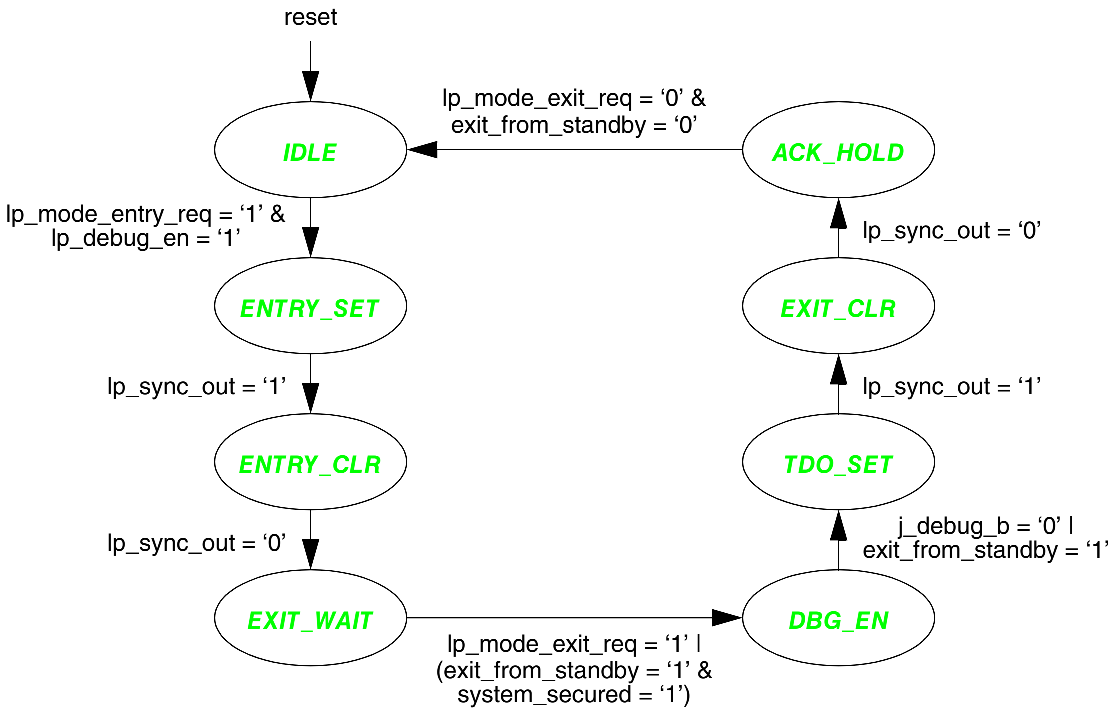

Figure 11-8. NPC_HNDSHK state machine

Table 11-19. NPC_HNDSHK state coding

Value	State	Description
000	IDLE	wait for low-power mode entry request assertion
001	ENTRY_SET	set NPC PCR sync bit
011	ENTRY_CLR	wait for NPC PCR sync bit clear
010	EXIT_WAIT	assert JTAG TDO pad and wait for low-power mode exit request assertion
110	DBG_EN	enable core debug mode
111	TDO_SET	deassert JTAG TDO pad and wait for NPC PCR bit set
101	EXIT_CLR	clear NPC PCR sync bit and return TDO pad to normal functionality
100	ACK_HOLD	wait for low-power mode exit request deassertion

11.8 Nexus Aurora interface

The Aurora interface allows Nexus protocol information to be transmitted serially at a high rate of speed over multiple Aurora lanes to provide advanced trace information from the device. The Aurora protocol handles the encoding of the data and striping the information across the lanes.

The Aurora information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports multiple trace clients within the MCU to all transmit information through a single Aurora port. Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client and, generally, can be individually enabled (both the type of messages and which clients). The following table shows the different types of Nexus messages.

Table 11-20. Types of Nexus messages

Message Type	Description
Program Trace	Nexus Program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership Trace	Ownership Trace provides information on process identification changes.
Watchpoint Trace	Watchpoint messages are generated anytime a watchpoint match occurs in the program or data flow. These can be programmed for many types of events within the MCU.
Device Identification	The device identification message allows information about the MCU to be transmitted on power up to allow tools to identify the target system MCU type.
Debug Status	Debug status message provides additional information that may be needed to reconstruct software execution. Information such as if the device has entered debug mode or low power mode.
Data Acquisition	Data Acquisition messages are an optional feature that allows software control of information to be transmitted.
Error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

The Nexus trace information can be output to internal memory or the parallel information can be serialized for transmission over a serial type interface through the Nexus Aurora interface.

11.8.1 Nexus Aurora overview

The IEEE-ISTO 5001 standard added a new type of Auxiliary trace port that supports a higher bandwidth. This new interface type uses the Aurora protocol to reformat the parallel Nexus messages into one or more output serial lanes of data, where a lane is defined as a 2-pin Low Voltage Differential Signals (LVDS) interface. The protocol handles striping the data onto the multiple lanes. Each lane uses an 8B/10B encoded LVDS drivers. The encoding allows the receiver to recover clocking information.

The Aurora physical interface is based on XAUI (10 Gigabit Attachment Unit Interface used in communication protocols) and covers the jitter, differential skew, inter-lane skew, and bit error rate requirements.

The Aurora protocol covers lane initialization and channel bonding for both simplex and duplex implementations. The current implementation implements a simplex output only connection from the MCU to the external tool.

The Aurora interface connects Nexus parallel trace output to an Aurora Protocol Engine (APE), the Aurora Lane Control (ALC) and the Nexus Aurora Physical interface (NAP). The following figure is the Aurora interface block diagram, where the number of lanes, n, is 2.

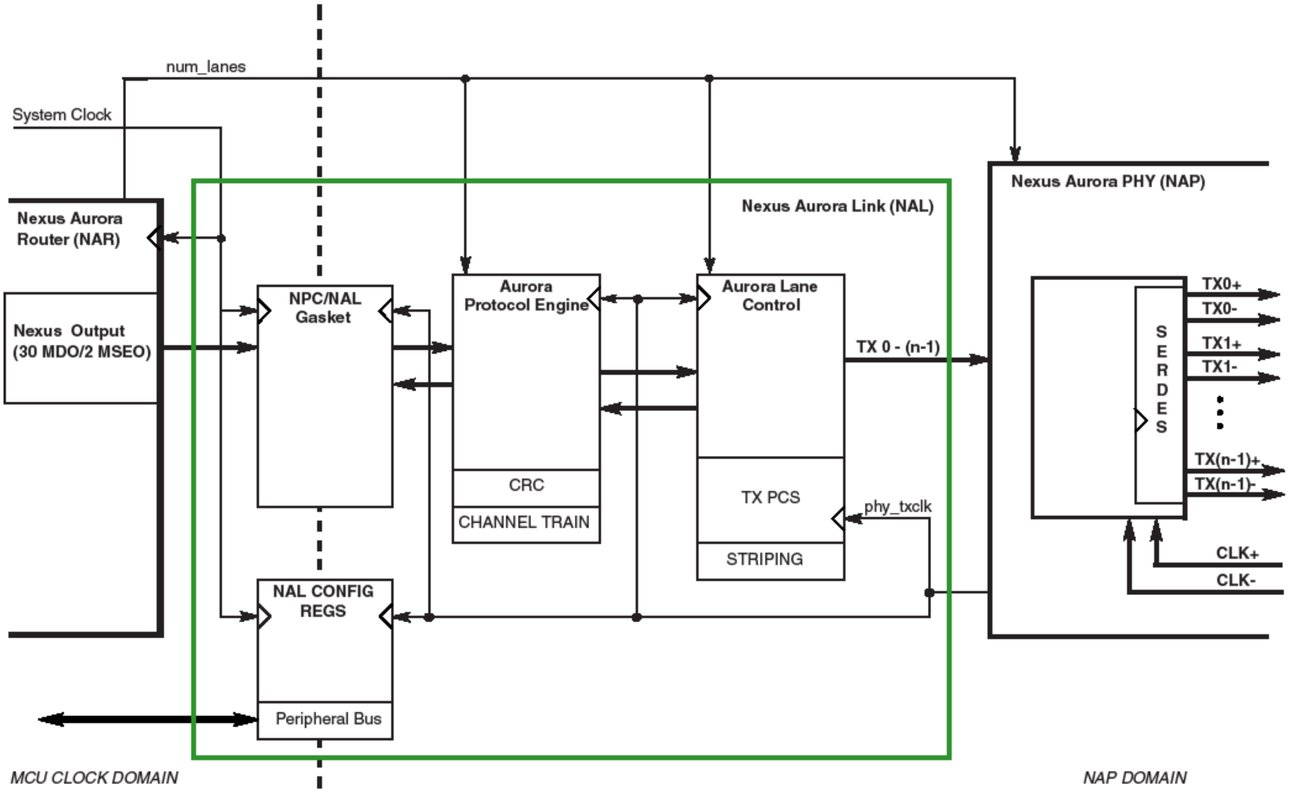

Figure 11-9. Aurora interface block diagram

The Nexus blocks do not have memory mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in JTAGC ACCESS_AUX block instructions. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The enable instructions for the different Nexus clients are shown in the following table. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 11-21. Nexus client JTAG enable instructions

Module	Enable instruction	Opcode
Cores (e200z4)	CORE_ENABLE	0x7C (10 bits)
NXMC modules	NEXUS_ENABLE	0x0 (4 bits)
NPC	NEXUS_ENABLE	0x0 (4 bits)
NAL	NEXUS_ENABLE	0xE (4 bits)

11.8.2 Nexus Aurora clocking

The supported clock frequency on the Aurora clock input has a valid range of 625 MHz to 1.25 GHz.

The Aurora interface requires the NAL and NAP to run with the same clock frequency as the cores for maximum bandwidth. For a 1.25 GBit/s data rate, the core frequency must be >=125 MHz.

11.9 Nexus Aurora Link (NAL)

The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer serializer and transmitter (no receiver). It includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol.

Debug data in the Nexus format from multiple clients is packetized into 32-bit format by the clients and then collected by the NPC. The NAL encodes the message data (8/10), stripes then across the lanes, and inserts Aurora control characters (such as start of message, end of message, idle, clock compensation characters and so on) around the payload. The NAL PCS drives the Nexus Aurora Physical (NAP) interface.

11.9.1 Chip-specific NAL information

Information about the NAL module on this chip includes the details in the following subsections.

11.9.1.1 Features

- Xilinx Aurora Protocol Specification V2.0 compliant.
- Two transmit-only lanes.
- Max data transmit rate = 2.5Gb/s with 2 transmit lanes running at 1.25 GHz.
- Cyclic Redundancy Checking (CRC) for error detection.
- Static (timer-based) channel training.
- Native and User Flow Control support.

11.9.1.2 NAL_GSR reset value

On this chip, the reset value of NAL_GSR is 0000_2400h.

See Nexus Aurora Link General Status Register (NAL_GSR) for details about this register.

11.9.2 Modes of Operation

The operating mode of the Aurora Link is determined first by the main SOC control signals (reset, scan_en). Its functional configuration is determined by the main SOC IO Port Control setting; functional operation is enabled by the PCR register in the NPC.

11.9.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Note that, since there is no tck-domain logic in the link itself, it is unaffected by treset.

Depending on the configuration, the link may power up upon exiting reset mode, if any Aurora lanes are enabled during reset.

11.9.2.2 Power-down

During purely functional operation, Nexus trace messaging is inhibited and clocks are disabled to the blocks of the Aurora Link. If the SOC exits POR-config with the Aurora channel disabled, the Aurora Link and any SerDes lanes dedicated to Aurora remain powered down. However, if the Link is powered down but the NPC is subsequently enabled with the Aurora channel active, the Link and dedicated SerDes lanes power up at this time.

11.9.2.3 Link Training

Before beginning functional operation, the Aurora Link must go through a training process to insure that both sides (SOC and debugger) can correctly reconstruct the transmitted data stream. The training process is outlined in the Aurora Protocol Specification, and consists of three sections: lane initialization, channel bonding, and channel verification. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL can be configured to initialize and train the Aurora link only in a simplex configuration. In training mode a timer based static-training method is used. The initialization and training sequence progresses from one step to the next via the use of programmable timers. A timer is programmed for each stage of training and as each timer expires, the training sequence can proceed to the next stage.

11.9.2.4 Aurora Transmit

During normal operation, the NPC will push data into the Aurora Link at a sufficiently high rate to insure that the link will not become data-starved even in its highest-bandwidth configuration (2 lanes operating at 1.25 GHz). The Link then performs the buffering, domain-crossing, data-packaging, and protocol translations to prepare the data stream for transmission through the NAP block.

11.9.3 Memory Map and Register Description

Configure the Aurora Link by programming the PCR register in the NPC and registers inside the NAL via JTAG accesses. Additional configuration registers within the link itself pertain to static training and debug modes. The link also has a read-only status register that provide information on channel training and general link operation.

- Nexus Aurora Link Status Register (NALGSR): The NALGSR register reflects general status of the Aurora link.
- Nexus Aurora Link Error Status Register (NALESR): The NALESR register reports error status in the Aurora link.
- NAL General Control Register (NALGCR): The NALGCR configures the behavior of the APE. It can be programmed to reset the Aurora channel, or to configure simplex/duplex initialization and to enable debug features.
- NAL Training Control Register (NALTCR): The NALTCR configures static training and timeout controls for the APE.

For more details about the register definition, see the Nexus Aurora Link (NAL) chapter.

11.10 Nexus Aurora PHY (NAP)

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. The NAP receives 8b/10b encoded data from the ALC block in the NAL and transmits this data onto a given PHY Lane's LVDS pads. The NAL performs lane striping with settings in the NAL and NPC specifying lane configuration. Each NAP lane consists of a Data Symbol Character Accumulator which registers the 10-bit character for that lane from the ALC on the rising edge of the NAL clock. A Serializer takes the 10-bit character and serializes it into the individual transmit data bits at the PHY clock rate to be transmitted via the LVDS output drivers to the external debugger receive channel.

NOTE

> The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive data side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking, and CRC checking in the received data stream.

The following figure shows a block diagram of the Nexus Aurora Physical (NAP) interface and the LVDS output drivers, where the number of lanes, n, is 2.

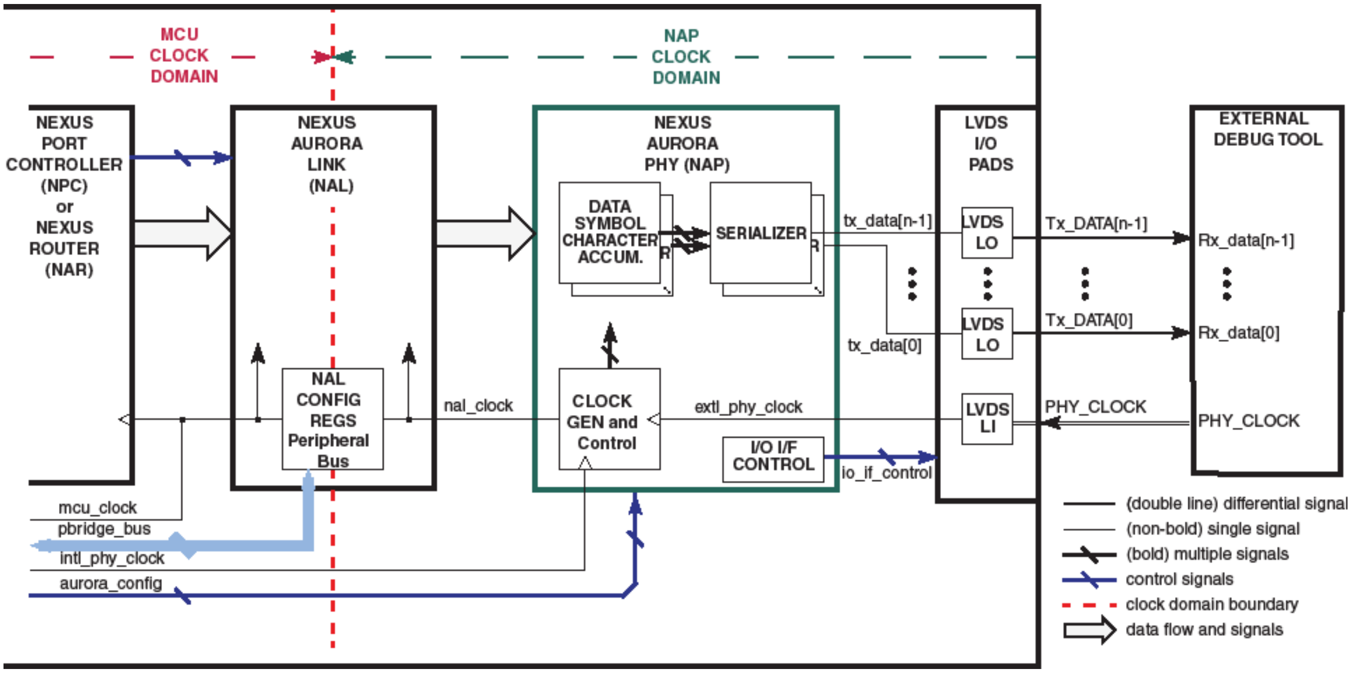

Figure 11-10. NAP block diagram

11.10.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.0 compliant
- Two differential transmit-only lanes
- Max data transmit rate of 2.5 Gb/s with two transmit lanes running at 1.25 GHz
- Simplex mode with static (timer-based) channel training

11.10.2 Modes of operation

The operating mode of the NAP is determined by the SoC control signals. The functional configuration is determined by the NPC PCR and NAL internal register settings; functional operation is enabled by the NPC.

11.10.2.1 Reset

During Nexus Reset all internal NAP resources are reset; all output ports are disabled, and all inputs are ignored. Since there is no SoC clock domain logic in the NAP itself, the NAP is unaffected by SoC system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

11.10.2.2 Disabled/Enabled

The NAP is disabled when it comes out of reset if the SoC is configured for pure SoC functional mode operation with Nexus trace messaging inhibited. The Aurora LVDS transmit lanes also remain powered down. In addition, any time the NAP block enable is negated the NAP is disabled and the LVDS transmit lanes powered down. Conversely, if the NAP is enabled when it comes out of reset or enabled sometime later after reset is negated, the NAP channels become active and the LVDS output lanes are powered on to transmit Nexus trace data.

11.10.2.3 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to insure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

11.10.2.4 Transmit

During Nexus trace output operation, it is the responsibility of the NPC to push data into the Aurora Link at a sufficiently high rate to insure that the link does not become data-starved even in its highest-bandwidth configuration. The NAL and NAP support only two Tx lane configuration. The number of Tx lanes available is configured at reset.

11.10.3 Signals

The following table correlates module-level signal names (shown in the NAP's dedicated chapter) and the corresponding chip-level names (shown in the Signal Description chapter).

Table 11-22. NAP signals

Module signal name	Chip signal name	Direction	Description
PHY_CLOCK	AUR_RXCLK_N	Input	Aurora Receive clock, Negative differential pair (LVDS)
	AUR_RXCLK_P	Input	Aurora Receive clock, Positive differential pair (LVDS)
TX Data0	AUR_TX0_N	Output	Aurora Transmit lane 0, Negative differential pair (LVDS)
	AUR_TX0_P	Output	Aurora Transmit lane 0, Positive differential pair (LVDS)
TX Data1	AUR_TX1_N	Output	Aurora Transmit lane 1, Negative differential pair (LVDS)
	AUR_TX1_P	Output	Aurora Transmit lane 1, Positive differential pair (LVDS)

11.11 Nexus clients

Nexus supports multiple trace clients within the device to all transmit information through a single Aurora port.

Table 11-23. Reference links to related information

Related module	Reference
e200z4 Nexus Support	e200z4 Nexus 3 Module
Nexus Crossbar Multi-Master Client (NXMC)	Nexus Crossbar Multi-master Client (NXMC)

The following table lists all possible clients that can create trace messages in the device and the SRC IDs used.

Table 11-24. Trace message SRC IDs used

Client	SRC ID used in trace messages
NPC (Aurora link overrun error message)	0xF
e200z4 Nexus	0x0
Nexus Crossbar Multi-Master Client 0 (DMA/SIPI/Ethernet)	0xC
Nexus Crossbar Multi-Master Client 1 (FlexRay)	0xD

11.11.1 e200z4 Nexus 3

The Nexus3 module provides real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

11.11.2 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE1149.1-2001 JTAG standard.

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) is implemented that monitors traffic into the master port of the XBAR. Two NXMCs are implemented, for the M5 and M6 master ports at the XBAR. Trace messages transmitted over the Nexus interface include which NXMC generated the message, as well as an identifier of the pre-concentrator source of the message.

This device has two available instances of the NXMC module:

- NXMC0 is attached to AHB master port M5 and traces accesses to DMA/SIPI/ Ethernet peripherals; the message SRC ID is Ch (see also Table 11-24)
- NXMC1 is attached to AHB master port M6 and traces accesses to the FlexRay; the message SRC ID is Dh (see also Table 11-24)

11.11.2.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001 standard. The following features are supported:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- Watchpoint trigger enable of data trace messaging
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

11.11.2.2 External signal description

This section details information regarding the standard ports and protocol. The NXMCpin interface provides the function of transmitting messages from the messages queues to the NPC. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$ (Event In)
- One $\overline{\text{EVTO}}$ (Watchpoint Event Out)
- Two$\overline{\text{MSEO}}$ (Message Start/End Out)
- 4 MDOs (Message Data Out) or Aurora Output
- One MCKO (Message Clock Out)

The output ports are synchronized to the Nexus output clock (MCKO).

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see Section 11.9.3.2, IEEE 1149.1 (JTAG) Test Access Port for details). A separate JTAG TAP controller is instantiated within the NXMC.

11.11.2.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in the following table. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 11-25. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 36
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 11-26)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 37
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 11-26)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See Table 11-27)
	14	14	ECODE	fixed	Error code (See Table 11-28)
Data Trace - Data Write	6	6	TCODE	fixed	TCODE number = 38

Table continues on the next page...

Table 11-25. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Message w/ Sync	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 11-26)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 39
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 11-26)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	8	8	WPHIT	fixed	Watchpoint source(s) number (See Table 11-35)

Table 11-26. Data trace size (DSZ) encodings (TCODE = 36,37,38,39)

DSZ	Transfer size
001	8-bit

Table continues on the next page...

Table 11-26. Data trace size (DSZ) encodings (TCODE = 36,37,38,39) (continued)

DSZ	Transfer size

011	32-bit
100	64-bit
000, 101-111	Reserved

Table 11-27. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110-1111	Reserved

Table 11-28. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description
13 to 8	7 to 0	
Source-ID (SRC): NXMC0 = 0xC, NXMC1 = 0xD		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved
000000	X1XXXXXX	Reserved
000000	1XXXXXXX	Reserved

11.11.2.4 NXMC register map

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See IEEE 1149.1 (JTAG) Test Access Port for details. The complete memory map appears in the following table.

Table 11-29. NXMC register map

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	$2	R/W	$04	$05
Development Control 2 (DC2)	$3	R/W	$06	$07
Watchpoint Trigger (WT)	$B	R/W	$16	$17
Data Trace Control (DTC)	$D	R/W	$1A	$1B
Data Trace Start Address1 (DTSA1)	$E	R/W	$1C	$1D
Data Trace Start Address2 (DTSA2)	$F	R/W	$1E	$1F
Data Trace End Address1 (DTEA1)	$12	R/W	$24	$25
Data Trace End Address2 (DTEA2)	$13	R/W	$26	$27
Breakpoint/Watchpoint Control Register1 (BWC1)	$16	R/W	$2C	$2D
Breakpoint/Watchpoint Control Register2 (BWC2)	$17	R/W	$2E	$2F
Breakpoint/Watchpoint Address Register1 (BWA1)	$1E	R/W	$3C	$3D
Breakpoint/Watchpoint Address Register2 (BWA2)	$1F	R/W	$3E	$3F
Reserved	$20-$3F	-	$40-$7E	$41- $7F

11.11.2.5 NXMC register descriptions

Detailed register definitions for the current NXMC implementation are described in the chapter Nexus Crossbar Multi-Master Client (NXMC).

11.11.3 Functional description

11.11.3.1 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of TRST and system reset de-assertion, after the JTAG ID register has been read by the tool.

11.11.3.2 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in NXMC register access via JTAG.

11.11.3.3 JTAG ID register

This JTAG ID Register (included in the NXMC module) provides key development attributes to the development tool concerning the NXMC block. This register is fixed and is accessed through the standard JTAG IR/DR paths.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	VERSION				FREESCALE DESIGN CENTER						SEQ#		AHBMM NEXUS ID#

Figure 11-11. JTAG ID register

The following table describes the JTAG ID register fields.

Table 11-30. JTAG ID field descriptions

Field	Description
31:28	Embedded Product Version Number, set to '0000'
27:22	Freescale Design Center ID Number, set to restore '100110'
21:20	Embedded Product Sequence Number, set to '11'
19:12	AHBMM Nexus Module ID, set to '01000101'
11:1	Manufacturer ID Number, set to '0000001110'
0	Fixed per JTAG 1149.1

11.11.3.4 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction (NEXUS-ACCESS =0x0) into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The NXMC module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the TRST pin or by cycling through the state machine using the TMS pin. The NXMC module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided, and the module disables the (drive inactive) auxiliary port output pins (MDO[30:0], MSEO[1:0], MCKO). NXMC registers are not available for reads or writes.

11.11.3.5 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the TRST pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

11.11.3.6 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction (NEXUS-ACCESS = 0x0) into the JTAG Instruction Register (IR).

Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to Table 11-29.

Reading/writing of a NXMC register then requires two passes through the Data-Scan (DR) path of the JTAG state machine. See details about the IEEE 1149.1-2001 TAP Controller Finite State Machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see Table 11-29) and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in the following figure and table.

	7	6	5	4	3	2	1	0
R W	Nexus Register Index							R/W
Reset	0	0	0	0	0	0	0	0

Table 11-32. JTAG DR field description for Nexus register access

Field	Description

Table continues on the next page...

Table 11-32. JTAG DR field description for Nexus register access (continued)

Nexus Register Index	Selected from values in Table 11-29
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
    a. During a read access, data is latched from the selected Nexus register when the JTAG state machine (see IEEE 1149.1-2001 TAP Controller Finite State Machine) passes through the Capture-DR state.
    b. During a write access, data is latched into the selected Nexus register when the JTAG state machine (see IEEE 1149.1-2001 TAP Controller Finite State Machine) passes through the Update-DR state.

11.11.3.7 Data trace

This section describes with the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001 standard.

11.11.3.7.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

11.11.3.7.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

11.11.3.7.3 Enabling DTM operation

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register via JTAG to enable data trace.
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC1 register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

NOTE

In case of enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) needs to be configured with right values in order to ensure correct DTM functioning.

11.11.3.7.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

NOTE

If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > DTM).

11.11.3.7.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

11.11.3.7.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

11.11.3.7.7 System bus cycle special cases

The system bus cycle special cases are shown in following table.

Table 11-33. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

11.11.3.7.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

11.11.3.8 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2003. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

11.11.3.8.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC1 Register. This bit is set either via JTAG write 1 access and cleared via JTAG write 0 access.

NOTE

> In case of enabling the watchpoint messaging, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported by using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a AHB access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too, as explained for DTM (in "System bus multi-master tracing").

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When a watchpoint source asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in the following figure and table.

Table 11-34. Watchpoint message format (fixed length = 18 bits)

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Table 11-35. Watchpoint source description

Watchpoint source (8 bits)	Watchpoint description
RRRRXXX1	reserved
RRRRXX1X	reserved
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

11.11.3.8.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in Figure 29.

Table 11-36. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

Chapter 12
Power Management

12.1 Overview

MPC5744P microcontroller includes a robust power management infrastructure that enables applications to select among various operational and low-power modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave RESET. This chapter gives an overview of the built-in power management features.

The power management infrastructure comprises the following modules:

- Power Control Unit (MC_PCU)
- Power Management Controller (PMC)

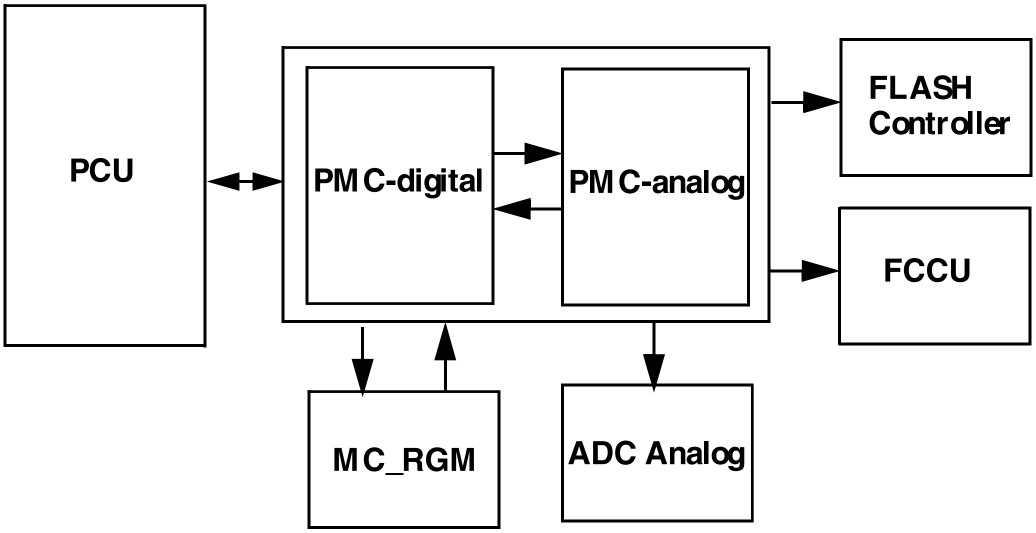

Figure 12-1. Power Management Overview

This chapter describes the modules interaction in brief. For complete details, see the respective module chapters.

12.1.1 Power Control Unit (PCU)

The Power Control Unit (PCU) is used mainly to map the Power Management Controller (PMC) registers into the PCU address space. These registers control the different low voltage detect options and power options for the device. On the MPC5744P device there is only one single power domain, therefore reducing power by switching off different areas of the device is not an option. There are low power modes which can be used, namely HALT and STOP for this purpose.

12.1.2 Power Management Controller (PMC)

The Power Management Controller implements a linear voltage regulator to generate the core logic supply from a 3.3 V (nominal) input supply and monitors various supply voltages of the MPC5744P chip for functional safety purpose. Depending on the supply voltages, power-on-reset (POR) and destructive resets are generated.

The PMC connects to the Reset Generation Module (MC_RGM), the Fault Collection Control Unit (FCCU) and the flash memory controller. The on-chip ADC receives signals from PMC for diagnostic purposes.

12.1.3 Supply Concept

MPC5744P provides on-chip regulator to derive the core supply from external 3.3 V supply. A power transistor must be added on the PCB. See the MPC5744P Data Sheet for specifics on this device. Alternatively, an external linear or switching regulator can be used. The analog supply needs to be protected from noise on digital supply at least by means of decoupling capacitor. Better filters can be used if they do not affect regulator stability. A separate regulator for analog supply is preferred.

The PMC monitors each supply voltage and releases the resets when they are within the limits of operating conditions. The power-on-reset can be generated on-chip or can be provided from external source, such as brown-out device.

Some supplies may already be connected internally inside the package depending on the package type, mainly in order to save pins in low pin-count packages.

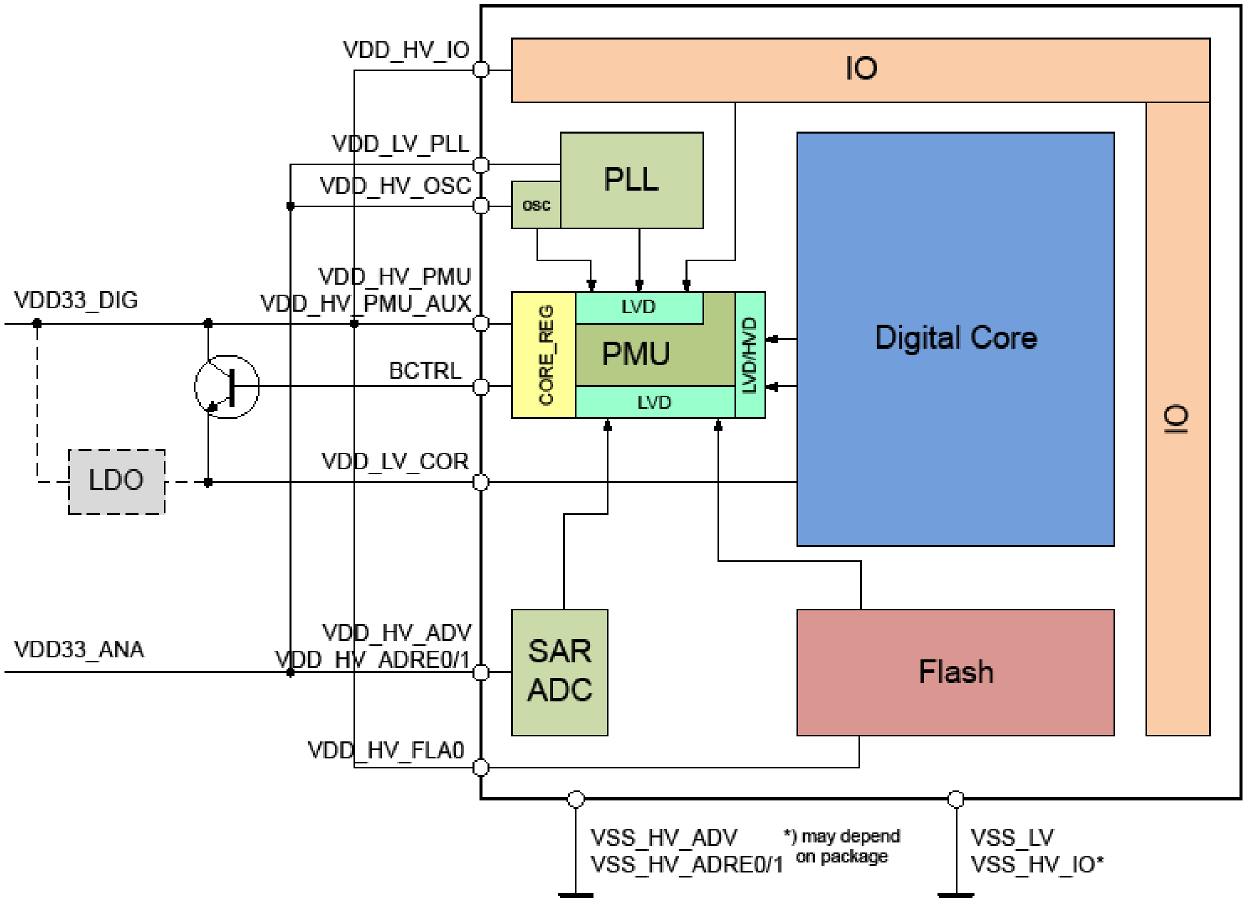

Figure 12-2. Supply concept

12.1.4 Power Modes

MPC5744P does not support ultra-low power modes that require power gating or separate power domains. The core logic implements stop and low frequency power saving modes, which may result in core current steps. The effect needs to be mitigated by a smoother frequency ramps instead of instantaneous change to avoid triggering LVD or HVD by under/overshoots.

12.1.5 External Supply

The internal supply regulator becomes inactive when an external Low Dropout Register (LDO) is used. The Bipolar Junction Transistor (BJT) should be removed in that case. It can be assumed that the internal regulator has no undesirable impact if ballast BJT is not present. The internal regulator can be switched off by setting the PMC module's PMCCR[INT_REG_BYPASS] field to 1.

12.1.6 Power Management Supply Description

The following table lists the PMC supply signals.

Table 12-1. Power management controller external signals

Name	Type	Description
VDD_HV_ADRE0	Reference	ADC0 High reference voltage
VDD_HV_ADRE1	Reference	ADC1 High reference voltage
VDD_HV_ADV	Supply	High voltage supply for the ADC modules
VDD_HV_IO	Supply	High voltage Power supply for the I/Os
VDD_HV_PMC	Supply	High voltage power supply for internal power management unit
VDD_HV_OSC0	Supply	High voltage power supply for the internal oscillator
VDD_LV_LFAST	Supply	Low voltage power supply for the LFAST module
VDD_LV_PLL	Supply	Low voltage power supply for the PLL module
VDD_LV_NEXUS	Supply	Low voltage power supply for the Nexus module
VSS_LV	Ground	Ground supply for the device / I/O. This is covering both VSS_LV and VSS_HV in case of exposed pad device.
VSS_LV_LFAST	Ground	Ground supply for the LFAST module
VSS_LV_NEXUS	Ground	Ground supply for the Nexus module
VSS_HV_IO	Ground	Ground supply for the device I/O.
VSS_HV_OSC0	Ground	Ground supply for the internal oscillator module
VSS_HV_ADRE0	Ground/ Reference	ADC0 Ground and low reference voltage
VSS_HV_ADRE1	Ground/ Reference	ADC1 Ground and low reference voltage
VSS_HV_ADV	Supply	Ground supply for the ADC modules

12.1.7 Voltage Monitoring

The PMC senses the supply voltages continuously to keep the chip in safe operating range. Destructive resets or alternatively, interrupts are triggered, when the voltage exceeds or falls below the limits defined by recommended electrical operating conditions.

12.1.7.1 Core Supply Monitor

The digital core supply range is compared with a low and high voltage limit.

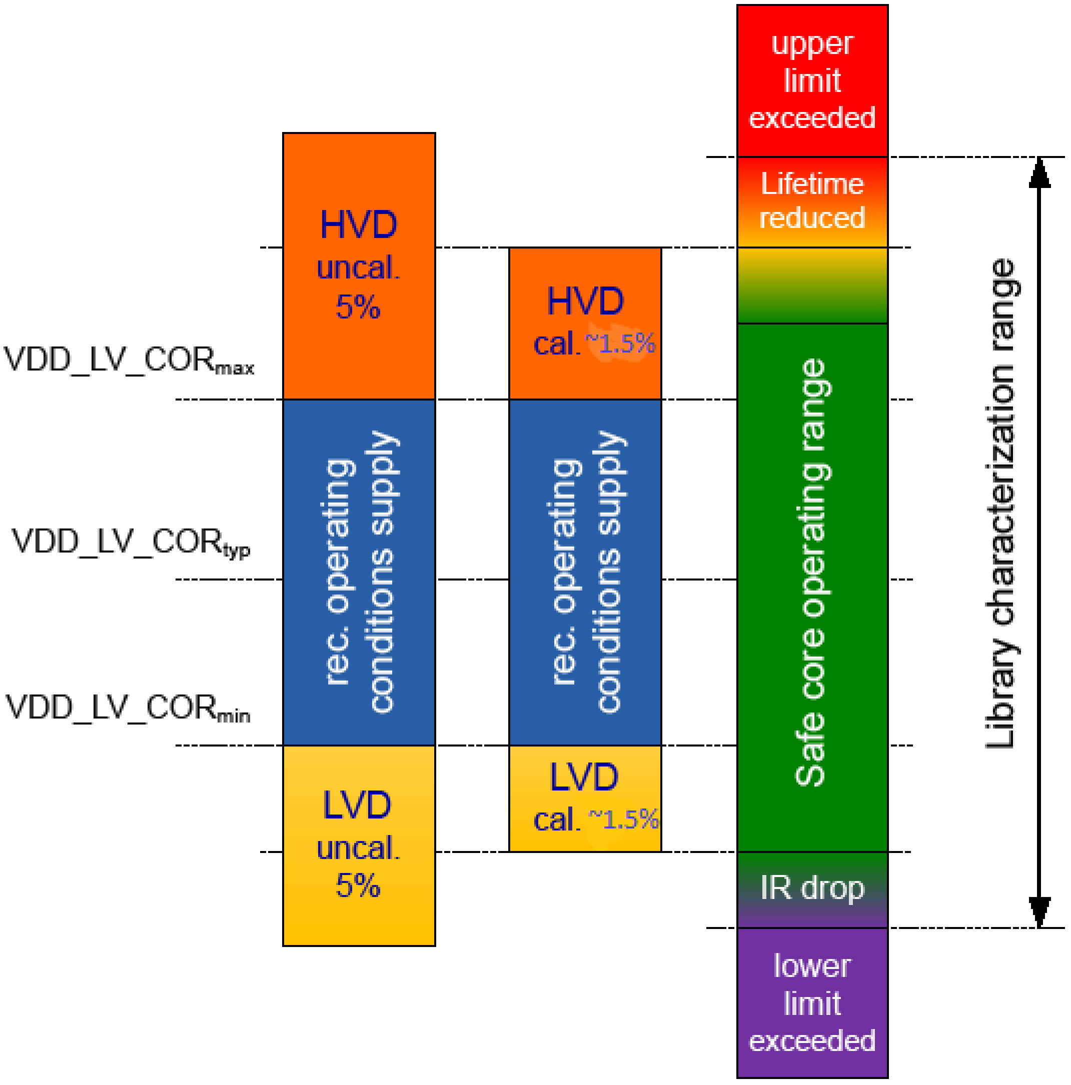

Figure 12-3. Core Supply Monitoring

The digital core is able to operate between the limits given by the MPC5744P Data Sheet. The lower limit is reduced by the amount of on-chip IR drop, that must be granted. The upper limit is defined by the beginning of lifetime degradation.

The available range for external supply voltage is further restricted by the tolerance of high (HVD) and low voltage monitors (LVD). See the MPC5744P Data Sheet for exact values. To ensure safe operating conditions for core the LVDs/HVDs are calibrated. Calibration of LVD/HVD takes places after the core is in functional safe operating range. It is performed in a way that LVD/HVD cover the allowed core operating range, i.e. by increasing the minimum value for LVD and decreasing the maximum value for HVD.

HVD checks the core supply for exceeding an upper limit. It has a 5% uncalibrated tolerance that can be reduced to ~1.5% by calibration. LVD checks the core supply for exceeding a lower limit. It has a 5% uncalibrated tolerance that can be reduced to ~1.5% by calibration.

If LVD and HVD are disabled, the external core supply can have an extended operating range. External voltage monitors shall be used in that case to ensure functional safety.

The core LVD/HVDs are duplicated for use at two different design points (LVD_CORE and LVD_CORE_BK or HVD_CORE and HVD_CORE_BK). The core supply is sensed at one external supply feed point and the IR drop critical point.

The core LVD/HVDs shall provide sufficient hysteresis or low-pass characteristic to prevent bouncing in case of short core supply over/undershoots.

12.1.7.2 IO, REG and other 3.3 V Supplies Monitor

All other 3.3 V, non-core supplies are compared to a lower limit only by means of LVDs. The following table lists the LVDs for the MPC5744P device.

All 3.3 V supplied modules must remain fully functional in an extended operating range that includes the LVD calibrated tolerance. The 3.3 V LVDs have 5% uncalibrated and 2% calibrated tolerance. Calibration takes place when the core supply is within a safe operating range. After calibration, the typical LVD value is centered within the recommended operating conditions low limit and the safe operating conditions low limit to provide margins for supply undershoots.

If LVDs are disabled, external voltage monitors shall be used to ensure functional safety. The LVDs shall provide sufficient hysteresis or low-pass characteristic to prevent bouncing in case of short 3.3 V supply undershoots.

Table 12-2. List of 3.3 V Low Voltage Detect Monitors

LVD Supply Monitored	Voltage Supply
LVD IO	3.3 V
LVD VDDREG	3.3 V
LVD VDDFLASH	3.3 V
LVD VDDADC	3.3 V

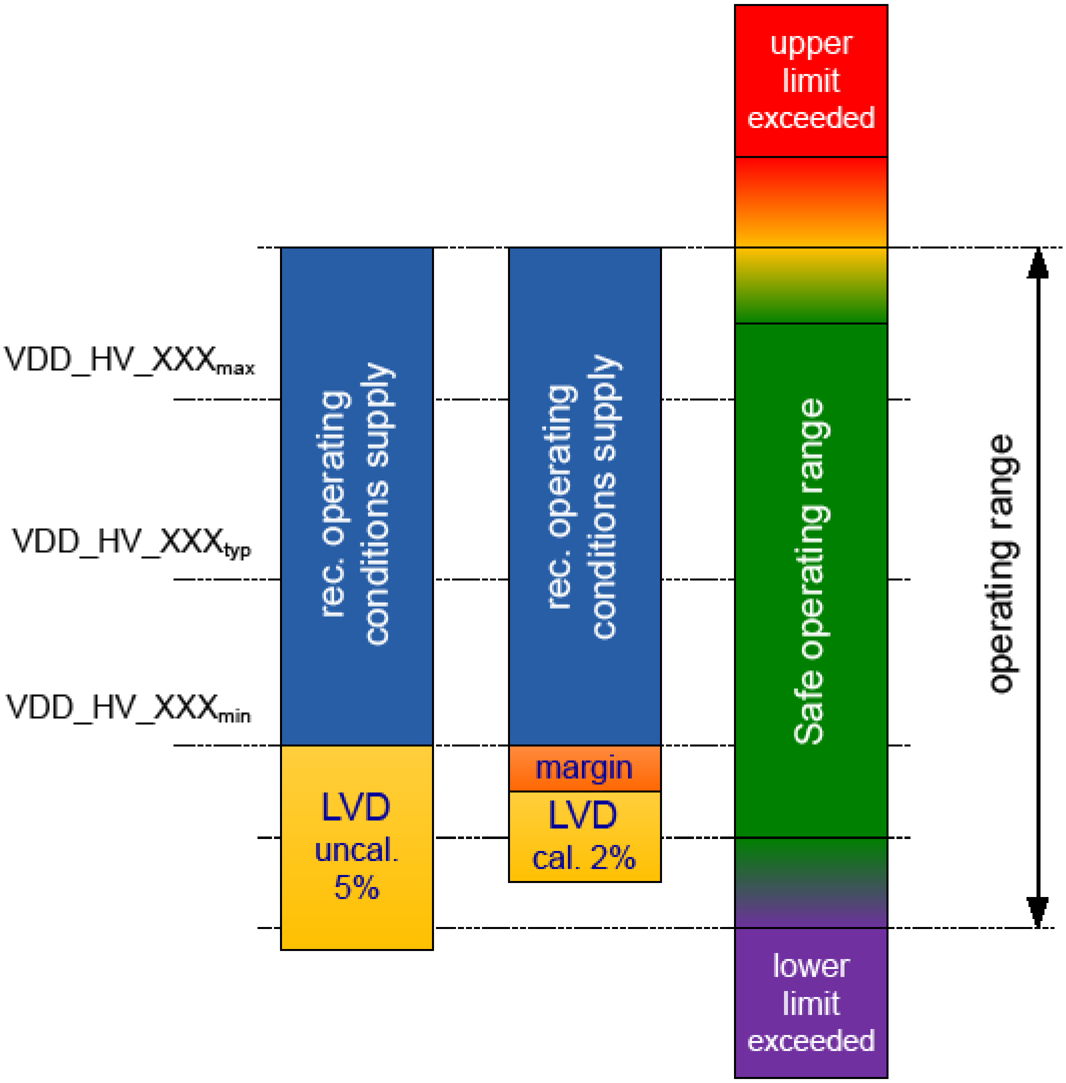

Figure 12-4. 3.3V Supply Monitoring

12.1.8 Power-on Reset

The Power-on Reset (POR) Generator is required to initialize the chip during supply rise. It is a voltage monitor which detects if a supply exceeds a defined threshold voltage level. The POR checks the core voltage supply VDD12_COR and the regulator supply VDD_HV_REG. When both supplies have a reliable level for the operation of the PMC and RESET generator, the LVDs/HVDs are activated.

The POR watches the rising edge of the supply before the recommended operating conditions are reached. The POR functions correctly even if the supply voltage is non-monotonic. It includes sufficient hysteresis to avoid bouncing in case of slow supply ramps. Within the safe operating conditions, the LVDs/HVDs take control over reset generation.

The POR must hold the device in reset regardless of how slow the supply rise time is, until the point at which the POR is designed to release. The rate of rise of a battery supply is described in an industry standard specification, ISO 16750-2. The slow ramp up / ramp down of battery supply and following VDD is specified as 0.9 V / sec.

12.1.9 Power-up Sequence

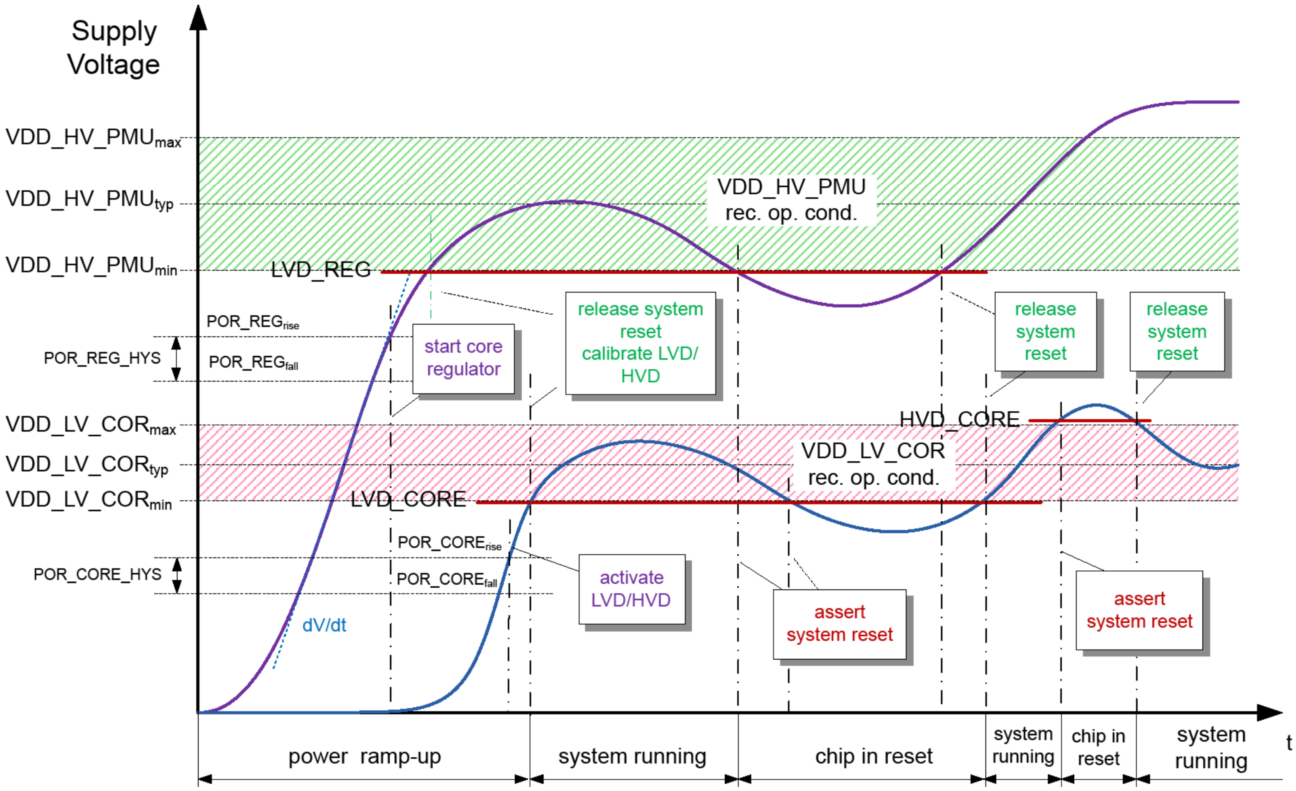

Figure 12-5. OFLAG timing during non-continuous counting

The power-up sequence runs whenever the system will get through a power cycle or external reset.

When the VDD33_REG voltage exceeds the POR_REG rising edge threshold, all 3.3V LVDs are reset to their uncalibrated state and armed. The core voltage regulator CORE_REG starts to work and the core supply voltage rises.

When the core voltage crosses the POR_CORE rising edge threshold, the core LVDs and HVDs are reset to their uncalibrated state and armed.

When the core supply and the regulator voltage reach their minimum value according to the recommended operating conditions, the system reset is released and the system boot process starts. The LVDs/HVDs are now calibrated to provide tighter limits for voltage over/undershoot detection.

As soon as core or any 3.3V supply falls below the limit of the corresponding LVD thresholds, a destructive reset is triggered. The system is held in reset state until all LVD threshold levels are exceeded again. If the core voltage exceeds the threshold of the HVD, a destructive reset is asserted. It is released when the core voltage falls below the HVD threshold.

When core or regulator supply fall below the POR_CORE or POR_REG falling edge limit, respectively, the system is reset and core supply is disabled. The chip will restart with a complete power-up cycle.

12.1.10 ADC Interface

The ADC interface provides the PMC internal voltages for diagnostic purpose. The analog multiplexer and the buffer is inside the PMC. The SAR ADC converts the selected voltage, which can then be evaluated by the CPU.

12.1.11 Safety Measures

The PMC implements a self-test architecture. The self-test can be triggered by test program or software. It is executed automatically with each power-cycle. The self-test will generate non-critical faults, which are collected in the FCCU module. The LVD/HVDs allow also error injection by SW, for artificially triggering an error in FCCU.

Parts of the PMC design that can act as a single point of failure are replicated, such as the analog voltage reference generation circuits.

Various internal voltages can be monitored during PMC operation, with assistance of the ADC.

The PMC provides a signal that keeps the I/O pads in a reset condition if either the core supply or the IO supply is out of the valid operating range.

Chapter 13
Clocking

13.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers
- Progressive Clock Switching

NOTE

This chapter covers only clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The clock (system clock) for the cores, memories, and debug logic is independent from the peripheral clocks. This independence allows the system clock to be a frequency-modulated clock to reduce electromagnetic emissions while preserving a precise clock for peripheral timer and communication functions. It also allows the system clock to be reduced during low computational activity periods while maintaining timer and communication link operation.

The MPC5744P boots from the 16 MHz internal RC oscillator (IRCOSC) and uses it as a backup clock (if a backup clock is enabled) in the event of a PLL or oscillator failure.

There are three possible ways to provide the source clock:

- External oscillator
- External crystal
- 16 MHz internal RC oscillator

From one of these input sources, the internal clocks are generated from one of the two PLLs, PLL0 and PLL1, PLL0_PHI and PLL1_PHI, respectively. These two clocks, along with the XOSC and IRCOSC, can be selected to drive system peripherals depending on the configuration of the Auxiliary Clock Selectors. The PHI1 output of PLL0 can also be used as the clock source for PLL1. A total of seven clock selectors allows developers to select the PLL reference clocks, drive various system peripherals with an independent clock source, and select a clock source to drive the CLKOUT signal for off-chip use. There is also one additional clock selector which is used exclusively for the system clock.

Each of the outputs of the module clock selectors has up to three dividers, which allows for even more clock frequency granularity with division factors up to 64 for a given group of peripherals. On selected outputs of the clock dividers are Clock Monitor Units (CMU) that are used to test the integrity of the clocks making sure that their frequencies stay within necessary operating limits. If any of the five CMUs detects an issue with the clock signal that is being monitored, an interrupt or system reset could be generated, depending on how the CMUs are configured.

13.2 Clock generation

The top-level clock generation architecture appears in the following figure. All clock selectors and dividers in the figure are located and programmed in the Clock Generation Module (MC_CGM). All dividers are integer dividers (1, 2, 3, …, n) with the ranges given in the diagram.

NOTE

CMU0…CMU4 in the figure use IRCOSC for their reference clock. However, the user can select XOSC as the reference in CMU0 for frequency measurement of IRCOSC.

Note: All dividers shown in the diagram (FCD not included) are integer dividers with a range of 1, 2, 3,...., n.
All clock dividers are 50% duty cycle.

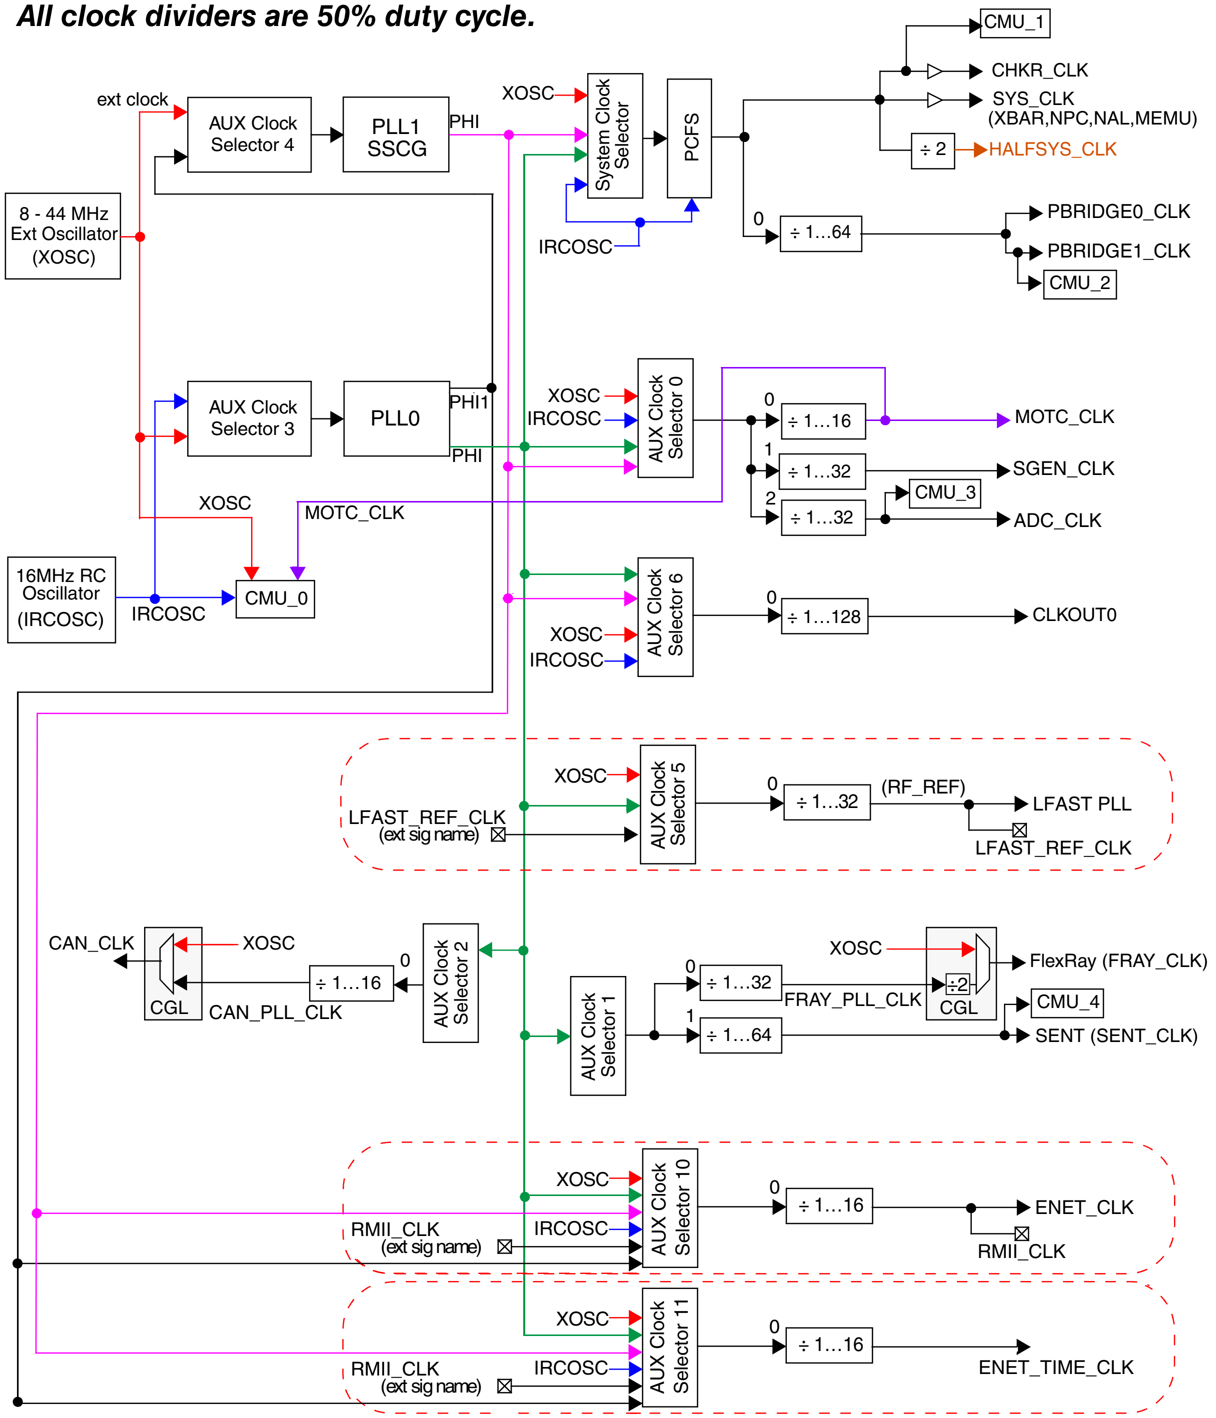

Figure 13-1. Clock generation

NOTE

PLL1 is routed on N15P devices into the AUX Clock Selector 0. It is recommended not to enable Frequency modulation on

PLL1 when it is being used as a clock source for AUX Clock Selector 0.

NOTE

See Figure 13-4 for LFAST clocking details.

13.2.1 MC_CGM registers

The following table shows the relationship between the clocks in Figure 13-1 and the MC_CGM registers.

NOTE

See the Clock Generation Module (MC_CGM) for specifics on register implementation.

Table 13-1. MC_CGM relationship to clocks

MC_CGM registers	Register description	Output clock	CMU
—	—	Checker Core Main Core RCCU_0 SYSCLK (XBAR, NPC, NAL, MEMU)	CMU_1[1]
		HALFSYS_CLK (SYSCLK ÷ 2)	-

Table continues on the next page...

Table 13-1. MC_CGM relationship to clocks (continued)

MC_CGM registers	Register description	Output clock	CMU
MC_CGM_AC6_SC	Aux Clock 6 Select Control		
MC_CGM_AC10_DC0 MC_CGM_AC10_SC	Aux Clock 10 Divider Configuration 0 Aux Clock 10 Select Control	ENET_CLK	—
MC_CGM_AC11_DC0 MC_CGM_AC11_SC	Aux Clock 11 Divider Configuration 0 Aux Clock 11 Select Control	ENET_TIME_CLK	—

1. Connected to the RCCU clock path (which is part of the Checker Core clock), after the branch of the clock line for Master and Checker Core and after the branch between Checker Core clock and RCCU clock.
2. Connected to the PBRIDGE1_CLK (downstream from the common part of the clock tree for the Peripheral Bridges)

13.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in the following table.

NOTE

The user is responsible to verify that these values are not exceeded.

NOTE

Each AIPS Bridge (PBRIDGE_0, PBRIDGE_1) is capable of clocking the AIPS interface of each peripheral slot individually at the XBAR frequency, or at the XBAR frequency divided by two.

Table 13-2. Maximum system level clock frequencies

System clock	Max frequency (MHz)
Cores, NPC, NAL, MEMU (CHKR_CLK, SYS_CLK)	200
XBAR (SYS_CLK)	200
PBRIDGE_0, PBRIDGE_1, SIPI, DMA_CH_MUX	50
Motor control (MOTC_CLK)	160
DMA, Interrupt Controller (HALFSYS_CLK)	100
ADCs	80
Sine Wave Generator (SGEN)	20
LFAST	320
FlexRay (FRAY_CLK)	80
FlexCAN (CAN_CLK)	80
SENT (SENT_CLK)	80
Ethernet (AHB clock)	100

Table continues on the next page...

Table 13-2. Maximum system level clock frequencies (continued)

System clock	Max frequency (MHz)
ENET_CLK	50
ENET_TIME_CLK	50 (integer ns period requirement)

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

13.3.1 JTAG Frequencies

The following table shows the maximum frequencies of the JTAG interface.

Table 13-3. JTAG Frequencies

Configuration	e200z4 Max Internal JTAG Frequency	Maximum External JTAG Frequency	Notes
Unconfigured clock	-	See electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
Clock configured to 180 MHz	90 MHz		JTAG usable at 1/2 CPU frequency

13.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to divide by two at power-on reset.

13.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (FMPLL)
- External Oscillator (XOSC)
- External Clock (EXTAL Bypass)
- 16 MHz Internal RC Oscillator (IRCOSC)

13.5.1 PLL

The PLL system in the MPC5744P is a Dual PLL that provides separate system and peripheral clocks. The PLLs are disabled after power on and must be enabled by software. The block diagram for the Dual PLL appears in the following figure.

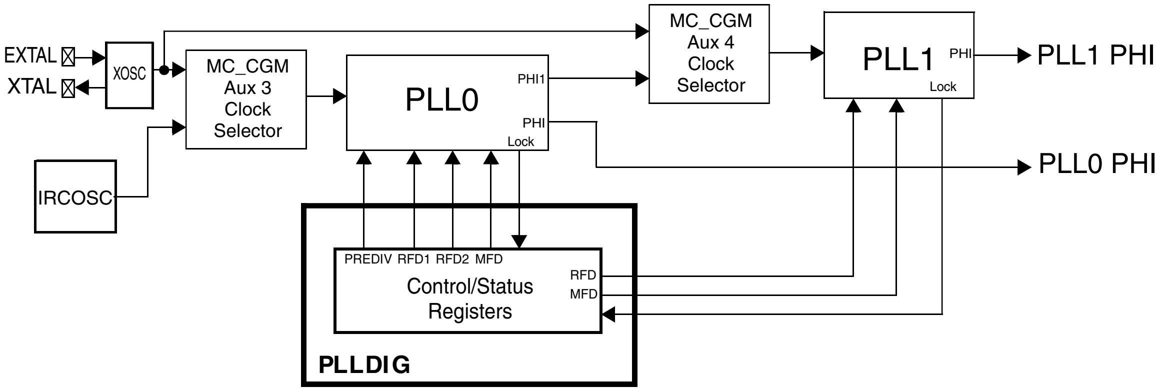

Figure 13-2. MPC5744P Dual PLL digital interface block diagram

13.5.1.1 PLL0 - base PLL (non-FM)

PLL0 is the primary PLL. This PLL is used to source a non-Frequency Modulated clock to the MPC5744P modules and also the reference clock to PLL1.

13.5.1.1.1 PLL0 input clocks

The possible input clock sources for PLL0 are the XOSC, IRCOSC, and EXTAL Bypass. The EXTAL Bypass input is the EXTAL pin. AUX Clock Selector 3 selects which input clock will be used as the source for PLL0. The selection between XOSC and EXTAL Bypass is made via the XOSC_CTL register of the XOSC module.

13.5.1.1.2 PLL0 output clocks

The output clocks from PLL0 are PHI and PHI1. The PHI output clock drives various peripheral clocks and the system clock when selected in the MC_CGM. The PHI1 output provides one of the input references for PLL1.

13.5.1.2 PLL1 - FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is typically used to drive the system clock. PHI is the output of PLL1 which drives the System Clock Selector and AUX Clock Selector 6 of the MC_CGM.

13.5.1.2.1 PLL1 input clocks

The possible input clock sources for PLL1 are XOSC, PLL0_PHI, and EXTAL Bypass. The EXTAL Bypass input is the EXTAL pin, which "bypasses" the XOSC output. AUX Clock Selector 4 selects which input clock is used as the source for PLL1. The selection between XOSC and EXTAL Bypass is made via the XOSC_CTL register of the XOSC module.

13.5.1.2.2 PLL1 output clocks

The output clock from PLL1 is the PHI clock, which can drive the system clock if the System Clock Selector of the MC_CGM is configured to do so. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

13.5.1.2.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the "Dual PLL Digital Interface" chapter.

13.5.1.3 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in the following table. All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 13-4. Dual PLL Digital Interface register reset values

Offset (hex)	Register	Reset Value (hex)
0008	PLL0DV - PLL0 Divider Register	0000_0000h
0028	PLL1DV - PLL1 Divider Register	0000_0000h

13.5.1.4 PLLDIG initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC.

1. Configure PLL0 and related modules.
    a. With PLL0 disabled, program PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select XOSC as source.

    b. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

    c. If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).

    d. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

2. Turn on XOSC and PLL0.
    a. Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<*mode*>_MC[XOSCON] = 1 and MC_ME_<*mode*>_MC[PLL0ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0 (PLL0:PHI output) as the sysclk.

    b. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.

3. Wait for the mode transition to complete.
    a. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

        - XOSC counter expires (if the new mode configuration changes MC_ME_<*mode*>_MC[XOSCON] = 1), and
        - PLL is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL0ON] = 1)

   b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

4. Configure PLL1 and related modules.

   a. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 1 which selects XOSC.

   b. Program PLL1DV[MFD] and PLL1DV[RFDPHI].

   c. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

5. Turn on PLL1.

   a. Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL0 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<*mode*>_MC[XOSCON] = 1, MC_ME_<*mode*>_MC[PLL0ON] = 1 and MC_ME_<*mode*>_MC[PLL1ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.

   b. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if re-entering the same mode.

6. Wait for the mode transition to complete.

   a. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

      - XOSC counter expires (if the new mode configuration changes XOSCON to 1), and

      - PLL1 is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL1ON] = 1).

   b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

13.5.2 External oscillator (XOSC)

The external oscillator (XOSC) is provided as a reference for the on-chip PLLs. It can also can be used as a clock source to the ADCs, SGEN, motor control modules, LFAST, and PLL reference as well as a system clock source. It is available for observation on either of the CLKOUT pins, and is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Reference clock to PLL0 and PLL1
- Reference clock to CMU0 (IRCOSC trimming)
- Option to drive the CAN and FlexRay protocol clocks directly from the XOSC
- Provides support for 8 MHz to 44 MHz crystal inputs

13.5.2.1 XOSC reset value

The following table shows the default reset value for the XOSC registers.

Table 13-5. XOSC register reset values

Offset	Register	Reset Value
0x00	XOSC_CTL-XOSC Control Register	0030_0000h

13.5.3 16 MHz internal RC oscillator (IRCOSC)

The microcontroller has a 16 MHz internal RC oscillator which is always enabled and can be used as the clock source for the PLLs. It is used as the clock source for the MC_RGM, FCCU, PIT, SWT, and SIUL2 input filters, and it can also be used as a clock source for the ADCs, SGEN, motor control modules, and system clock. The IRCOSC is the default system clock after reset. The register interface is used for user trimming of the oscillator.

13.5.3.1 IRCOSC register interface

This device has a dedicated digital interface for the IRCOSC. The digital interface provides a register for fine tuning the IRCOSC frequency by the user. Other registers allow reading of the settings of IRCOSC temperature sensor, voltage regulator and capacitor trimming values that are set by the factory. The IRCOSC is always enabled when the device is powered.

13.5.3.2 IRCOSC trimming

The IRCOSC requires trimming to meet accuracy requirements. During the initial phases of a reset sequence triggered by a power-on or destructive reset, the IRCOSC runs at its untrimmed frequency value. A trim value that was determined during factory test, and subsequently stored in flash memory, is loaded during reset via the SSCM to the IRCOSC_CTL[USER_TRIM] (see the "IRCOSC Digital Interface" chapter for details).

13.6 Peripheral clocks

The following figure shows the clock distribution to the core and peripheral modules.

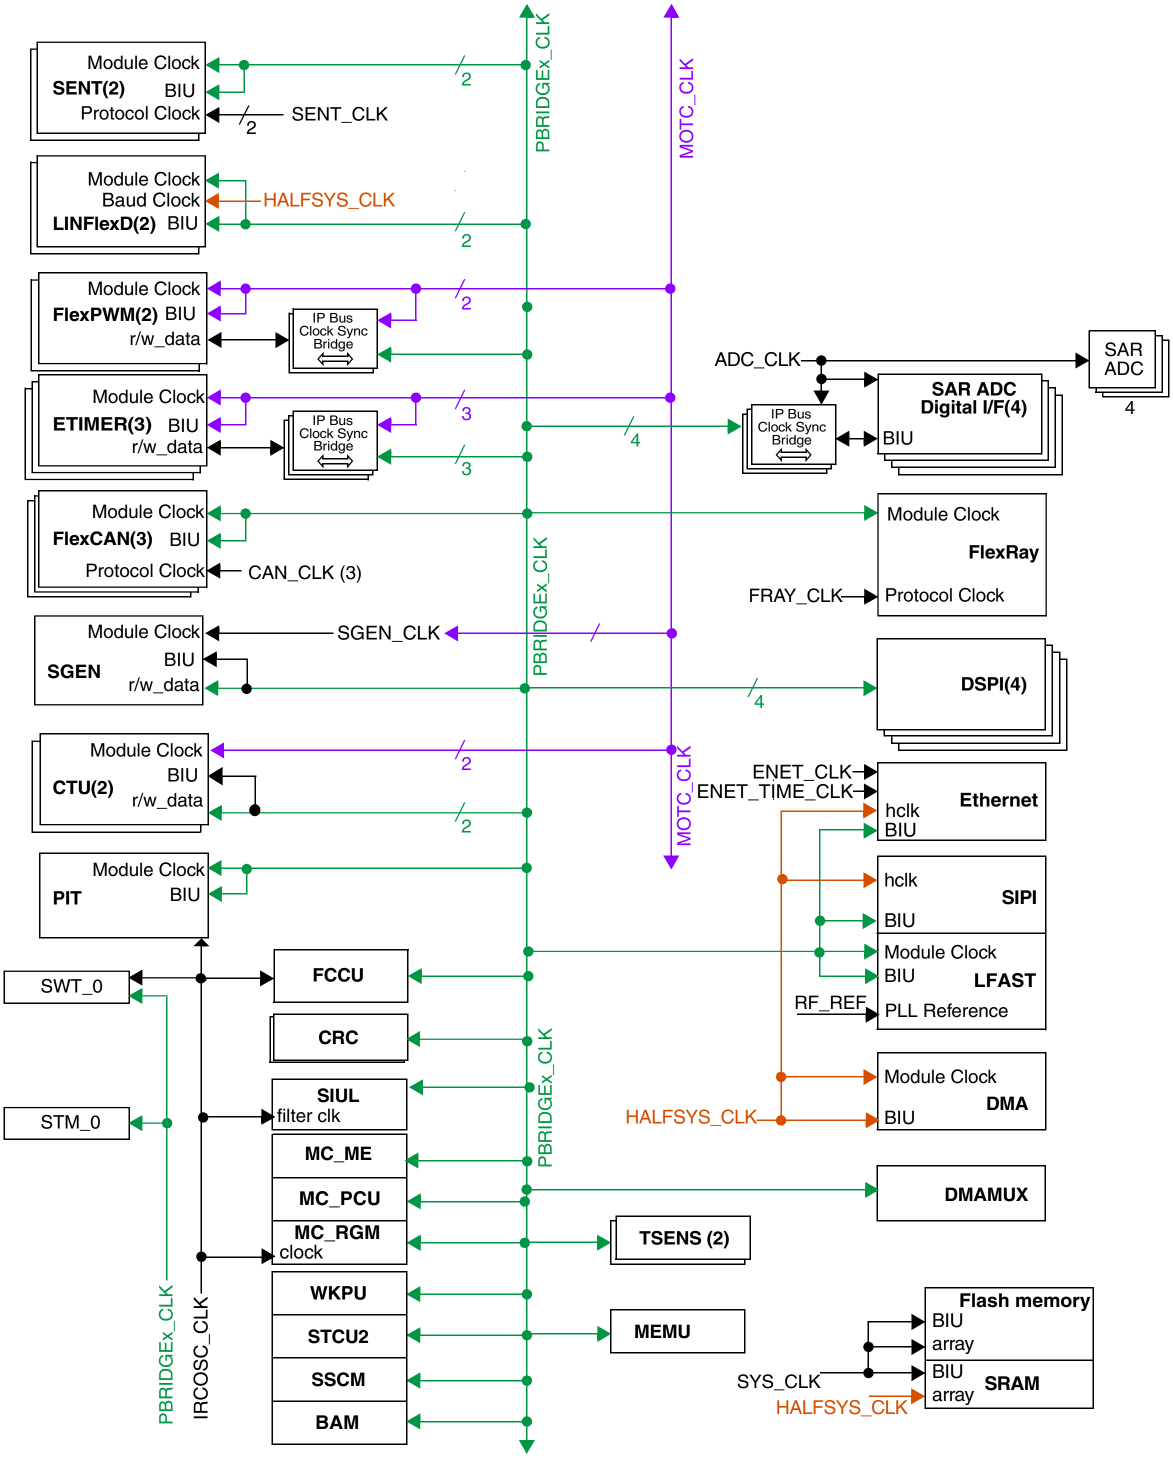

Figure 13-3. Clock distribution

NOTE

Before Disabling the clock from root (source), make sure that all the peripherals that are using the clock are switched OFF or at least that clock is not selected as source of Peripheral clock. For Example:- In FlexCAN when XOSC is selected for the

CAN Engine Clock Source (FLEXCAN_CTRL[CLKSRC]), before disabling FlexCAN Peripheral Clock, the user must ensure XOSC is enabled during the target mode transition i.e. XOSC must be enabled for the target mode. After the FlexCAN Peripheral Clock is switched OFF user can disable XOSC clock.

13.6.1 LFAST clocking

The MPC5744P includes an LFAST module to support high speed device communications. A single LFAST PLL, which requires a 10-20 MHz reference, supports high speed operation of the LFAST module. For low speed LFAST operation, the reference clock is used directly by the LFAST module.

The LFAST PLL requires a 20 MHz reference. The source may be the PLL0_PHI or the external oscillator (XOSC) or input from the external LFAST device via the LFAST_REF_CLK package pin. When this reference clock is generated internally, it can also be output on the LFAST_REF_CLK pin. The LFAST_REF_CLK pin connection appears in the following figure. Input/Output direction of the LFAST_REF_CLK pin is controlled by the MSCR in the SIUL2.

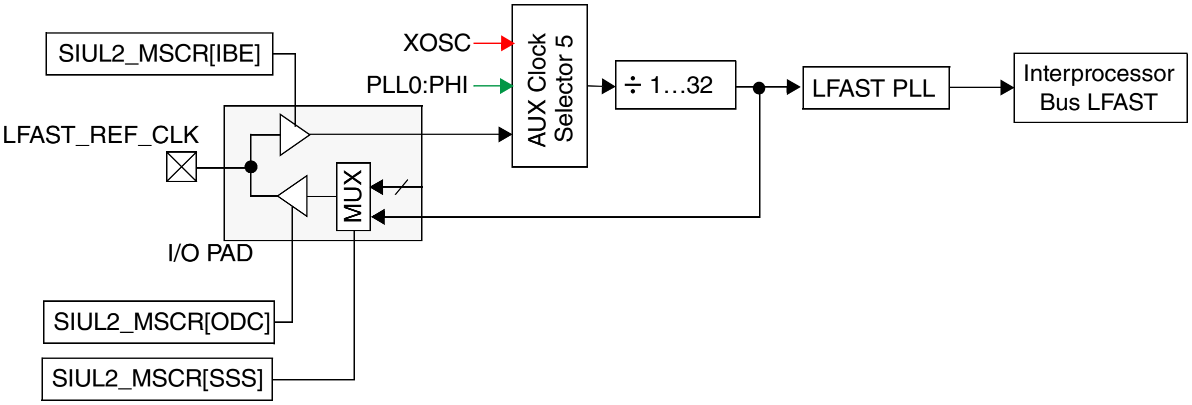

Figure 13-4. Device LFAST SysClk

13.6.2 FlexRay clocking

The FlexRay protocol clock is sourced from either the non-FM PLL0_PHI clock or the external oscillator (XOSC). Select between these sources by programming the FlexRay module's FR_MCR[CLKSEL] field.

- When using the external oscillator clock, a 40 MHz crystal is required for proper operation.
- When using PLL0_PHI, the MC_CGM_AC1_DC0 register must be configured to provide 80 MHz on FRAY_PLL_CLK for proper operation.
    - The frequency of the PLL source must be double the frequency of the XOSC source because the PLL has a less stable duty cycle.
    - The FlexRay module itself divides the PLL frequency to provide a steady, 50% duty cycle, 40 MHz clock internally.
    - This internal FlexRay divider is driven automatically when FR_MCR[CLKSEL] is 1. The user cannot change this internal divider or select it for the XOSC source.

13.6.3 FlexCAN clocking

The CAN_CLK is generated from either the XOSC or PLL0_PHI clock. The PLL0_PHI clock can be divided by a value written to the CGM_AC2_DC register in the MC_CGM. The output of this divider (CAN_PLL_CLK) drives one of two inputs of a multiplexer. The other input is driven by XOSC. FlexCAN_CTRL1[CLK_SRC] selects whether CAN_PLL_CLK or XOSC clock drives the output of the multiplexer for the CAN_CLK.

13.7 Clock monitoring

For all safety critical clocks, the microcontroller detects a missing clock or incorrect frequency. To achieve this clock monitoring units (CMUs) are used. Each CMU is programmed independently. The IRCOSC is used as the clock monitor references. Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

13.7.1 CMU configuration

This section explains the CMU configuration.

Figure 13-5 shows the block diagram for CMU0 on the MPC5744P.

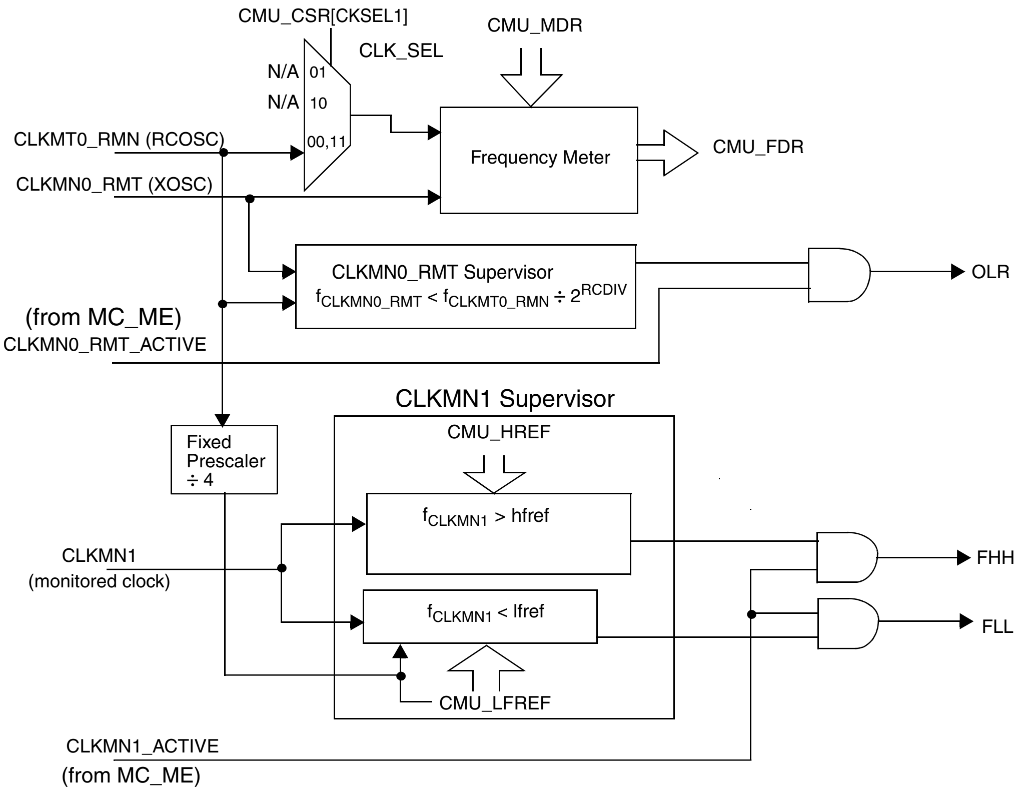

Figure 13-5. CMU0 Block Diagram

Figure 13-6 shows the block diagram for CMU[1:4] on the MPC5744P.

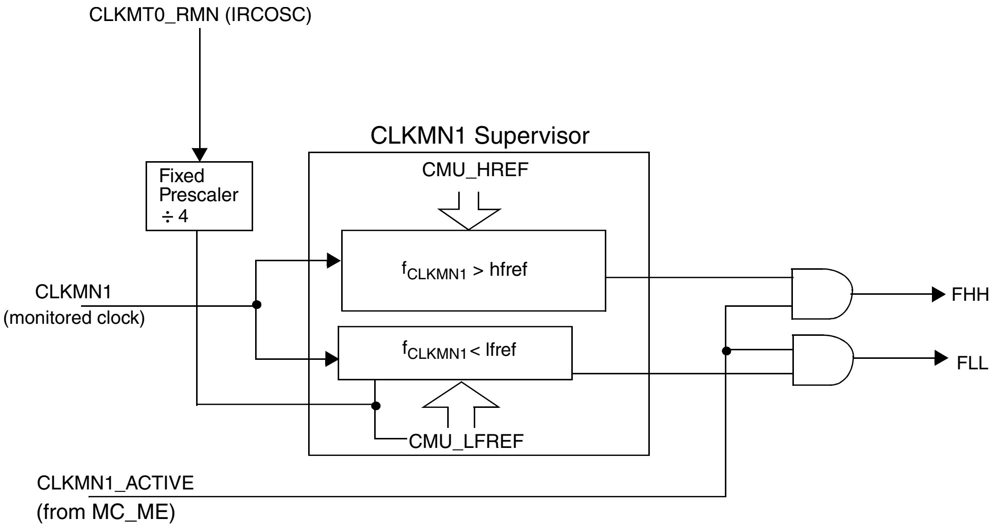

Figure 13-6. CMU[1:4] Block Diagram

13.7.1.1 Clock input sources

Table 13-6 shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU0 implements the XOSC monitor. CMU0 uses the IRCOSC clock to measure if the XOSC is too low. CMU0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 13-6. Clock input sources

Clock module	Monitored clock
CMU0	MOTC_CLK (CLKMN1 for CMU0), XOSC, IRCOSC
CMU1	CHKR_CLK
CMU2	PBRIDGE0_CLK, PBRIDGE1_CLK
CMU3	ADC_CLK
CMU4	SENT_CLK

13.7.1.2 CMU registers and field availability

Table 13-7 specifies which registers and fields are available on a given CMU for this device.

Table 13-7. CMU registers availability

Address Offset	Register	CMU	Note
0x0000	CMU_CSR	All	CMU_CSR[SFM] and CMU_CSR[CKSEL1] apply in CMU0 only. For all CMU instances on this chip, CMU_CSR[RCDIV] resets to 11b.
0x0004	CMU_FDR	CMU0	—
0x0008	CMU_HFREFR	All	—
0x000C	CMU_LFREFR	All	—
0x0010	CMU_ISR	All	CMU_ISR[OLRI] is in CMU0 only.
0x0014	Reserved	—	—
0x0018	CMU_MDR	CMU0	—

13.7.2 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set, and an interrupt is generated, if enabled. Frequency limits are give in the MPC5744P Data Sheet.

13.7.3 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

13.7.4 System clock monitors

A CMU is assigned to monitor the frequency of the checker core, both Peripheral bridges, motor control, ADC and SENT clocks (see Figure 13-1).

13.7.4.1 Monitor control and behavior

Software can program an upper and lower limit of the expected clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set, and an interrupt will be generated, if enabled. The default condition of the clock monitor is disabled.

13.8 Loss of clock sources behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and it provides several options for reaction to a loss of clock in the application. Figure 13-7 provides a high-level view of the logic of the loss of clock sources.

13.8.1 Loss of PLL/XOSC clock

As shown in Figure 13-7, each loss of lock signal from the PLL and XOSC failure signals are monitored by the FCCU. For the event when a clock failure occurs, the FCCU can be programmed to generate a short or long reset sequence or simply to generate an interrupt. In the case of the interrupt, only the unpredictable free running clock is still provided by the PLL. There is no automatic system clock switch in this case, and the user is required to program the switch through the Mode Entry module (MC_ME). Therefore, it is strongly recommended that the interrupt reaction to a PLL loss of lock is not selected when the PLL is used as the source of the system clock.

If a long or short reset is selected: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states, and the system clock is switched to the IRCOSC.

13.8.2 Loss of IRCOSC clock

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot and backup clock, a failure is a catastrophic failure.

Each CMU's FHH and FLL event indicators are connected solely to the FCCU. In this regard, CMU_0's connection to the FCCU in the following figure represents all CMU instances.

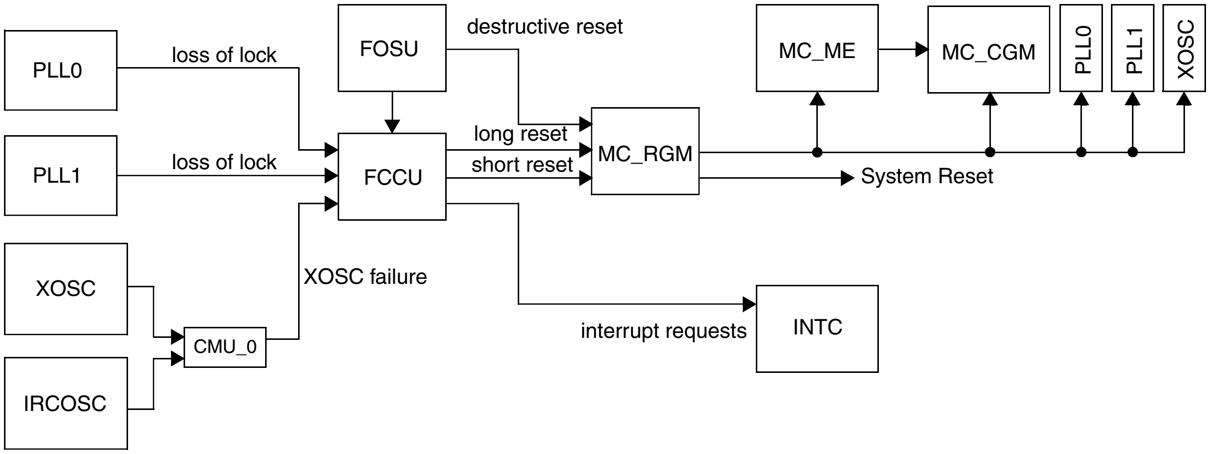

Figure 13-7. Loss of clock sources

13.8.3 PLL loss of lock interrupt

Always write 1 to both PLL0CR[LOLIE] and PLL1CR[LOLIE] to keep the loss of lock interrupt function enabled.

The main interrupt functionality is determined by the FCCU via fault input NCF[24] for PLL0 and fault input NCF[25] for PLL1.

Chapter 14
e200z4d Core Complex Overview

14.1 Introduction

The main computational shell consists of Main Core_0, which uses an e200z4251n3 core. A second core, referred to as Checker Core_0s, is an e200z424 core that is a true subset of the e200z4251n3 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0, executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to insure that Main Core_0 is executing correctly. This chapter provides overviews of the e200z4251n3 core and the e200z424 core.

The e200z4251n3 and the e200z424 cores are very similar. The register set for these cores is identical. The e200z424 core differs in hardware from the e200z4251n3 in that no Instruction Cache, Data Cache, or D-memory is implemented.

14.2 Overview of e200z4251n3 and e200z424 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power architecture.

The e200z4251n3 and e200z424 are dual-issue, 32-bit Power VLE compliant designs with 32-bit general purpose registers (GPRs).

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

The e200z4251n3 and e200z424 cores implement the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in PowerISA 2.06, a separate document. The base *PowerISA 2.06* fixed-length 32-bit instruction set is not directly supported.

The e200z4251n3 and e200z424 processor cores integrate a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

A Nexus Class 3+ module is integrated into each e200z4251n3 and e200z424 processor core.

A Memory Protection Unit is integrated in each e200z4251n3 and e200z424 processor core.

14.3 Features

The following is a list of some of the key features of the e200z4251n3 and e200z424 processor cores:

- Dual issue, 32-bit *PowerISA 2.06*-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
- Load/store unit
  - 2 cycle load latency
  - Fully pipelined
  - Misaligned access support
- 32-bit General Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit System buses
- Local Data Memory (DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z4251n3 core: 64 KB DMEM
  - e200z424 core does not contain either Instruction or Data MEM
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction and Data Cache
  - e200z4251n3 core: 8 KB ICache, 4 KB DCache
  - e200z424 core does not contain either Instruction or Data Cache
- Embedded Floating-point APU (EFPU2) supporting single-precision floating-point operations
- Lightweight Signal Processing Extension (LSP) APU to support real-time SIMD fixed-point embedded numerics operations using the GPRs
- Performance Monitor APU supporting execution profiling

- Nexus Class 3+ Real-time Development Unit
- Power management
    - Low power design with extensive clock gating
    - Power saving modes: halt, stop, wait
    - Dynamic power management of execution units, caches and Local memories
- Testability
    - Synthesizeable, MuxD scan design
    - ABIST/MBIST for arrays
    - Built-in LBIST unit

14.4 Microarchitecture summary

The e200z4251n3 and e200z424 processor cores utilize a five stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/EA Calc, Execute0/Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single clock instruction execution for most instructions. The following figure shows a block diagram of the e200z architecture.

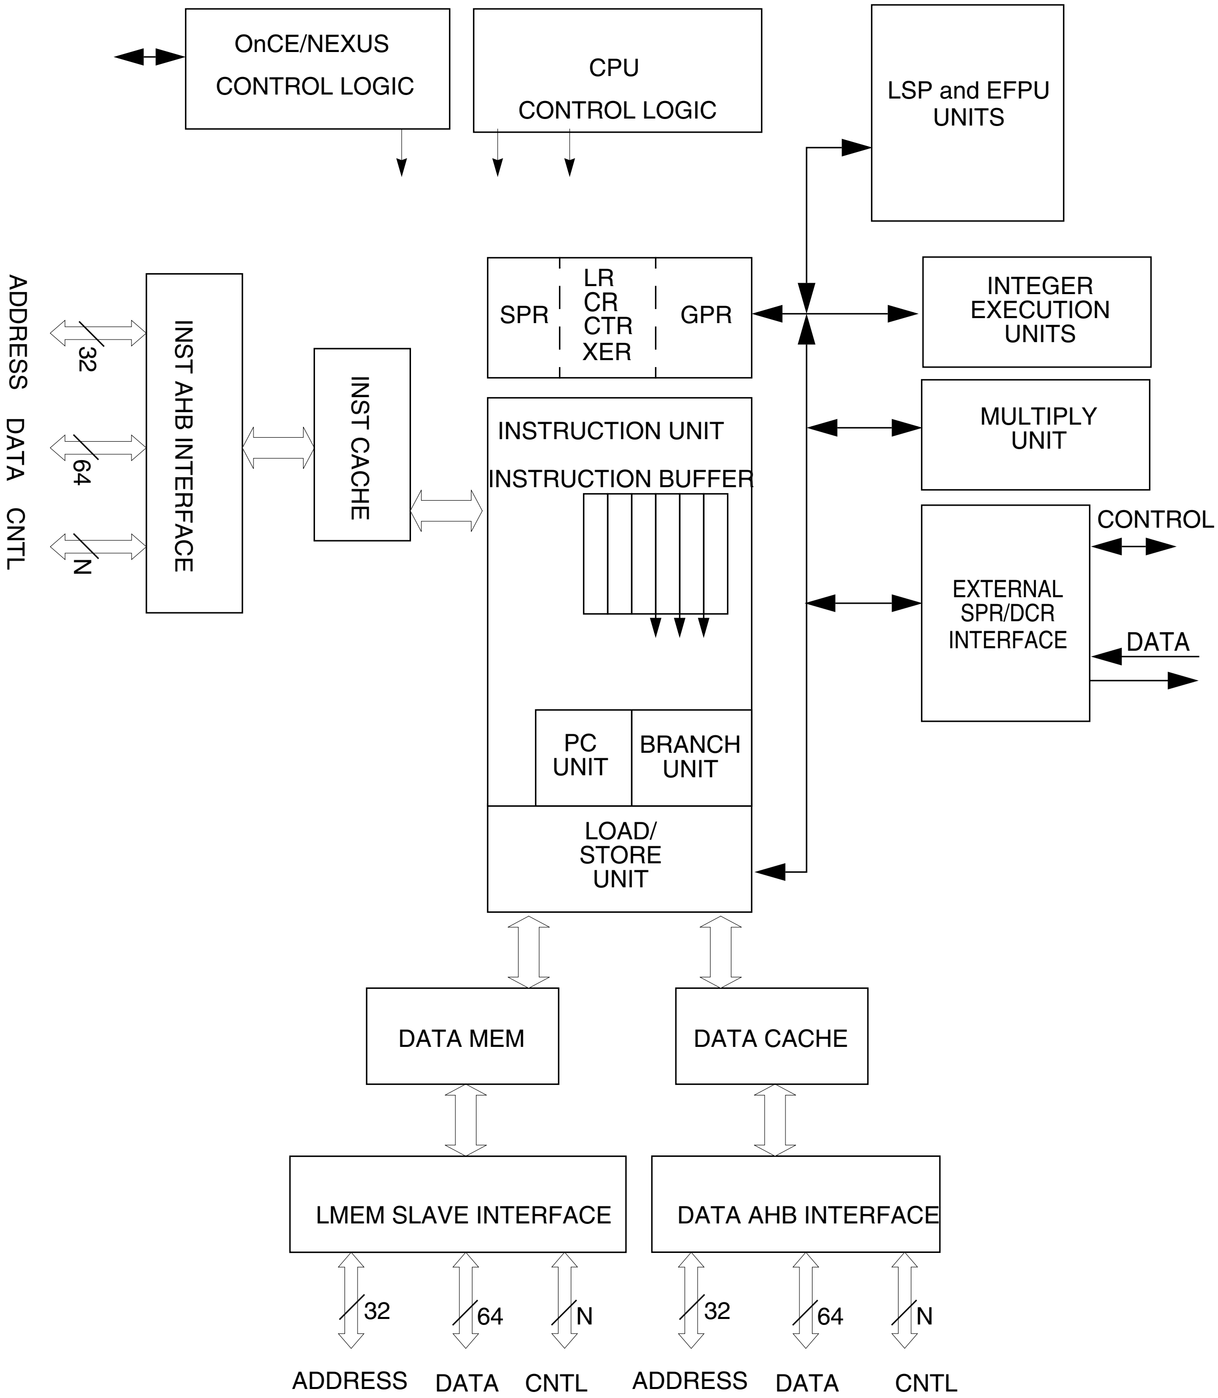

Figure 14-1. e200z block diagram

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. Integer EU1 also supports hardware division and a 32x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clocks for correctly predicted branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations and use 64-bit data transfers when possible. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the Power architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The LSP APU supports vector instructions operating on 16- and 32-bit fixed-point data types. The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats, supports scalar single-precision floating-point operations, and operates in a pipelined fashion. The general purpose register file is used for source and destination operands, and a unified storage model is used for scalar single-precision floating-point data types of 32-bits and the normal integer type. Low latency fixed-point and floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided, and most operations can be pipelined.

14.4.1 Instruction unit features

The features of the e200z4251n3 and e200z424 Instruction units are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds up to eight 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single cycle execution of successfully predicted branches

14.4.2 Integer unit features

The e200z4251n3 and e200z424 integer units support single cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zero's function
- 32-bit single cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clocks with minimized execution timing (EU1 only)
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

14.4.3 Load/Store unit features

The e200z4251n3 and e200z424 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

14.4.4 EFPU2 Floating-Point Unit features

The EFPU2 embedded floating-point unit supports pipelined operation of most floating-point operations, allowing a throughput of one FP operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion <-> single-precision format

- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined scalar floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput
- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results
- Floating-point Divide and Square root logic operating in 13 (FP div) and 11 (FP sqrt) clocks

14.4.5 LSP Lightweight Signal Processing Unit features

The LSP APU is designed to accelerate signal processing applications normally suited to DSP operation.

- LSP instructions operate on the 32-bit GPRs
- Supports SIMD integer operations: arithmetic, logical, shift
- Supports SIMD rounding, saturation, pack, unpack, merge, extract, select for efficient data manipulation
- Supports SIMD multiply/multiply accumulate/ dot product operations
- 16-, 32-, and (limited) 64-bit signed and unsigned integer data types
- 16- and 32-bit signed fractional support (1.15, 1.31 representations)
- Guarded 32-bit and 64-bit signed fractional support (9.23, 33.31, and 17.47 representations)
- Single-cycle throughput for all instructions (except frac divide)
- Supports fractional divide operations (32/32->32)
- Specialized operations such as field manipulation and count-leading
- Supports specialized load/store operations with integrated data manipulation
- Multiple addressing modes supported including circular and bit-reversed addressing
- Sustained throughput of up to 2 16x16-bit multiply/accumulate operations per cycle.

14.4.6 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit Process Identifier
- Bypass capability for individual access types
- Maskable Address and Process Identifier

- Programmable Memory Attributes
- Entry Invalidation Protection
- Write-Once Option
- Alternate Debug Breakpoint/Watchpoint function

14.4.7 Cache features

The features of the caches are as follows:

- 2-Way Set Associative Harvard Instruction and Data Caches
  - e200z4251n3: 8 KB ICache, 4 KB DCache
  - e200z424: no ICache, no DCache
- Writethrough Support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Support for Way locking
- Support for Write allocation policies
- Support for multi-bit EDC with Correction/Auto-invalidation capability for the I and D caches
- Hardware Debug Cache Invalidate Support for the Data Cache
- Software and Hardware Debug access to cache tag, status and data storage via dedicated control registers

14.4.8 Local memory features

The features of the local data memories are as follows:

- Local data memories (DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z4251n3: 64 KB DMEM
  - e200z424: no IMEM, no DMEM
- 1 wait-state slave DMEM read access, 1 wait-state slave DMEM write access
- 64-bit local bus to CPU supporting 0 wait-state CPU access
- Support for multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

14.4.9 Performance Monitor Unit features

The features of the performance monitor include:

- Four configurable 32-bit performance monitor counters, each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use
- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events
- Multiple selectable event types including # of clocks, CPU stall cycles, # of instructions completed, # of interrupts taken, # of memory accesses (by type), # of instruction or data cache misses, # of cycles with 0, 1, or 2 instructions issued, # of instructions in a given class completed (ldst, branch, integer, FP, and so on), and cache linefills

14.4.10 e200z4251n3 system bus features

The features of the e200z4251n3 system bus interface include:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address buses, 64-bit instruction-side and data-side system buses
- Data interface provides separate uni-directional read and write data buses
- Support for HCLK running at a slower rate than CPU clock

14.4.11 e200z424 system features

Checker Core_0 is implemented using an e200z424 core. When enabled, Checker Core_0s is used in lock step with Main_Core_0. The e200z424 core can only be enabled or disabled by the user. For this device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main Core 0.

The e200z424 core is identical to the e200z4251n3 with five exceptions:

- IMEM memory array is not present
- ICache memory array is not present
- DMEM memory array is not present
- DCache memory array is not present
- e200z424 has a pair of system bus interfaces, which are driven/sampled by the delayed lock step logic

Chapter 15
Core Detailed Description

15.1 Overview of the e200z4251n3 core

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The e200z4251n3 is a dual-issue 32-bit *Power ISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z4251n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *Power ISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed-point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs support register pairing in order to support vector instructions defined by the LSP APU. These instructions operate on a vector pair of 16-bit or 32-bit data types, and deliver 16-bit vector and 32-bit scalar results. A wide variety of data manipulation, multiply, multiply/accumulate, and dot product instructions along with specialized memory access instructions allow a sustained throughput of up to two 16x16-bit multiply/accumulate operations per cycle.

The e200z4251n3 core integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z4251n3 core contains an 8 KB Instruction Cache, and a 4 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

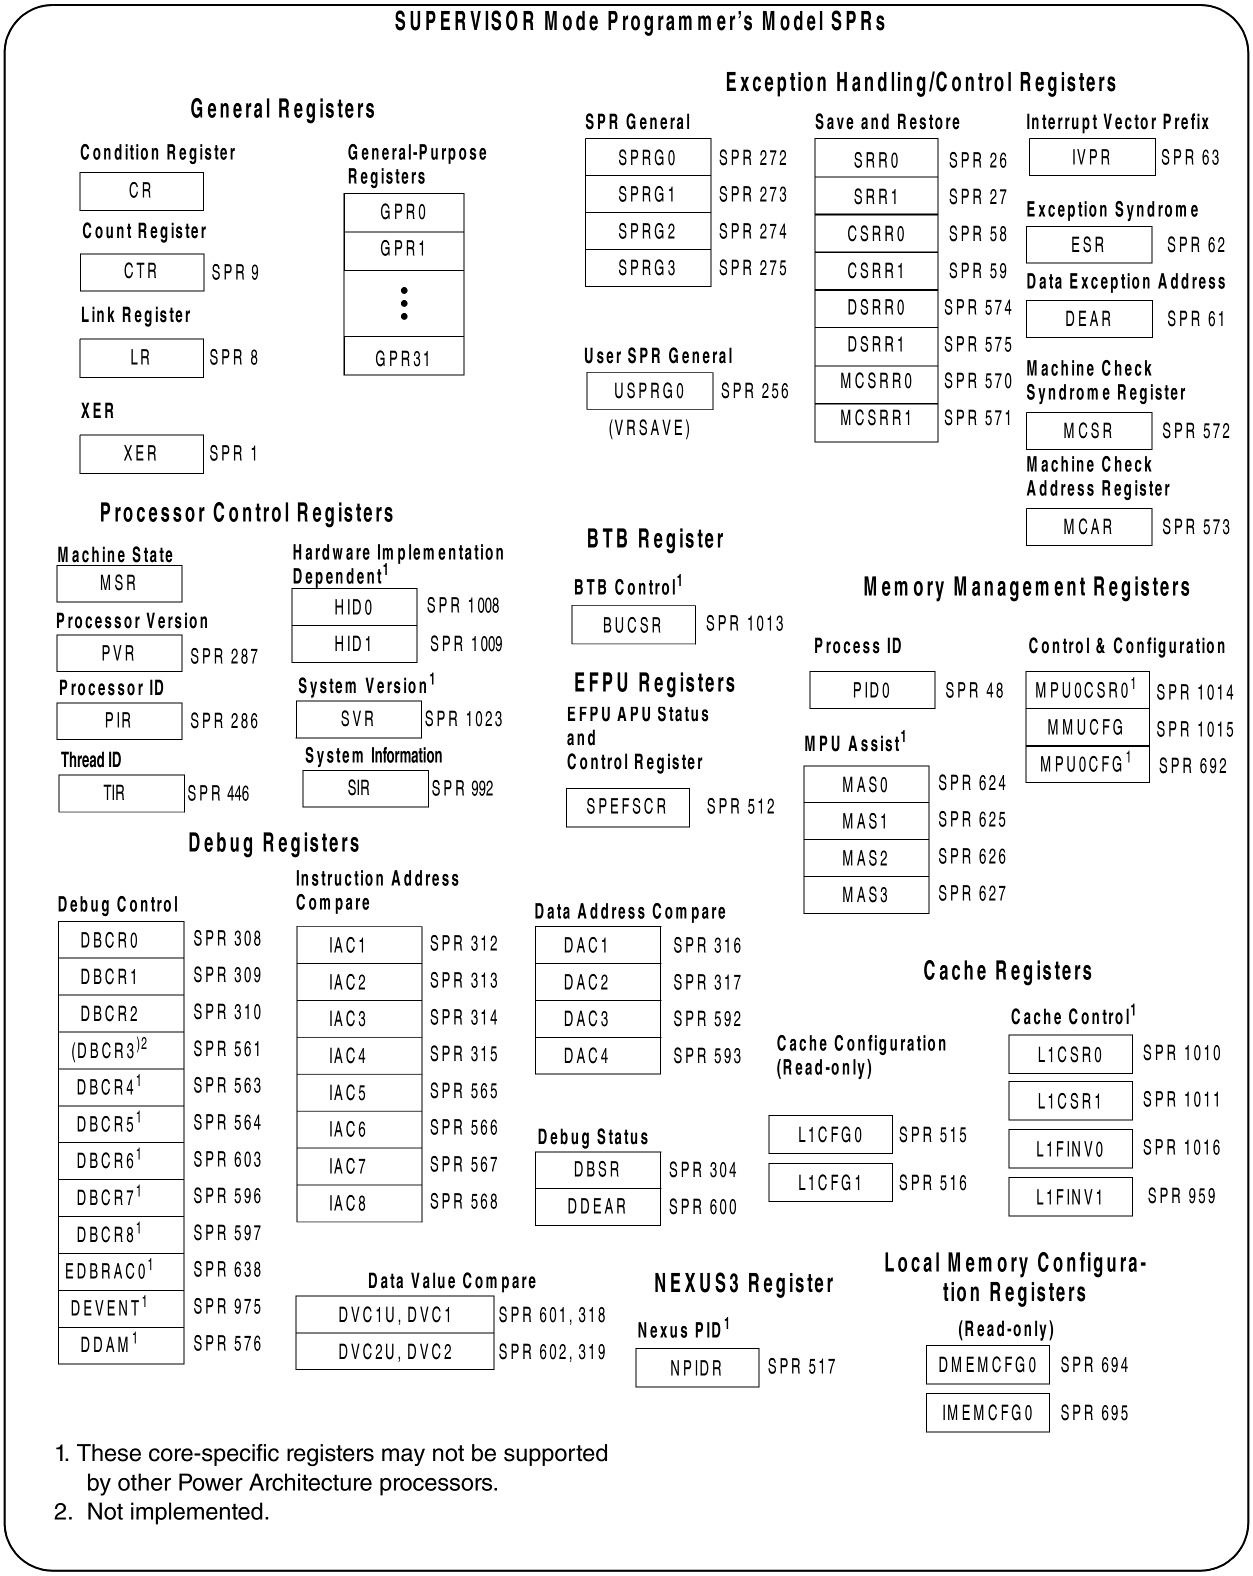
A Memory Protection Unit that protects various instruction and data memory areas is also included.

15.2 Register model

This section describes the registers implemented in the e200z4251n3 core. The *Power ISA 2.06* architecture defines register-to-register operations for all computational instructions.

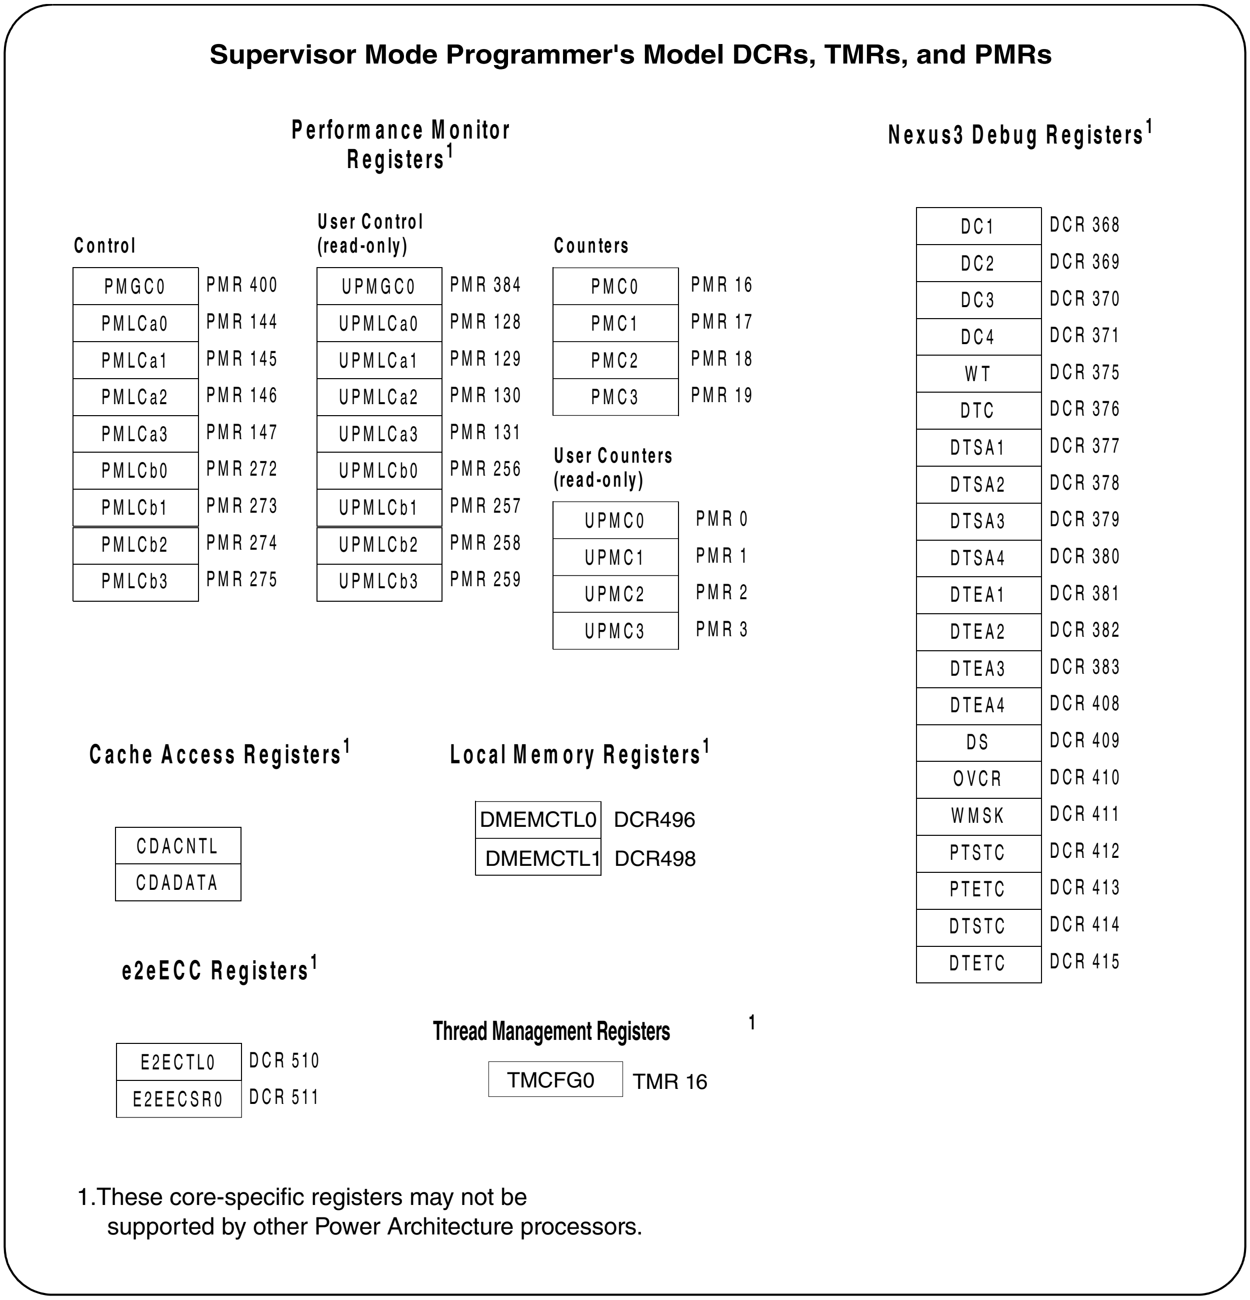
e200z4251n3 extends usage of the general purpose registers to support EFPU /LSP APU operations on the 32-bit GPR registers.

Figure 15-1 and Figure 15-2 show the complete e200z4251n3 register set, all of which are accessible in supervisor mode. Figure 15-3 and Figure 15-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).



1. These core-specific registers may not be supported by other Power Architecture processors.
2. Not implemented.

Figure 15-1. e200z4251n3 Supervisor Mode Programmer's Model SPRs



1.These core-specific registers may not be supported by other Power Architecture processors.

15.2.1 Branch Unit Control and Status Register (BUCSR)

The BUCSR register is used for general control and status of the branch target buffer (BTB). The BTB is detailed in . The BUCSR is shown in the following figure.

<table>
<tr><td colspan="22">0</td><td>BBFI</td><td colspan="3">0</td><td colspan="2">BALLOC</td><td>0</td><td colspan="2">BPRED</td><td>BPEN</td></tr>
<tr><td>0</td><td>1</td><td>2</td><td>3</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td><td>10</td><td>11</td><td>12</td><td>13</td><td>14</td><td>15</td><td>16</td><td>17</td><td>18</td><td>19</td><td>20</td><td>21</td><td>22</td><td>23</td><td>24</td><td>25</td><td>26</td><td>27</td><td>28</td><td>29</td><td>30</td><td>31</td></tr>
</table>

SPR — 1013; Read/Write; Reset — 0x0

Figure 15-5. Branch Unit Control and Status Register (BUCSR)

The BUCSR fields are defined in the following table.

Table 15-1. Branch Unit Control and Status Register (BUCSR)

Bits	Name	Description
0:21 [32:53]	-	Reserved
22 [54]	BBFI	Branch target buffer flash invalidate. When written to a '1', BBFI flash clears the valid bit of all entries in the branch target buffer; clearing occurs regardless of the value of the enable bit (BPEN). Note: BBFI is always read as 0.
23:25 [55:57]	-	Reserved
26:27 [58:59]	BALLOC	Branch Target Buffer Allocation Control. This field controls BTB allocation for branch acceleration when BPEN = 1. Note that BTB hits are not affected by the settings of this field. 00 Branch Target Buffer allocation for all branches is enabled. 01 Branch Target Buffer allocation is disabled for backward branches. 10 Branch Target Buffer allocation is disabled for forward branches. 11 Branch Target Buffer allocation is disabled for both branch directions.
28 [60]	-	Reserved
29:30 [61:62]	BPRED	Branch Prediction Control (Static). This field controls operation of static prediction mechanism on a BTB miss. When a branch is predicted as taken, fetching of the predicted target location will be performed for branch acceleration. BPRED operates independently of BPEN, and with a BPEN setting of 0, will be used to perform static prediction of all unresolved branches. 00 Branch predicted taken on BTB miss for all branches. 01 Branch predicted taken on BTB miss only for forward branches. 10 Branch predicted taken on BTB miss only for backward branches. 11 Branch predicted not taken on BTB miss for both branch directions. **NOTE:** BPRED functionality is not supported in e200z4xxx processor cores due to its short pipe stages.
31 [63]	BPEN	Branch target buffer prediction enable. When the BPEN bit is cleared, no hits will be generated from the BTB, and no new entries will be allocated. Entries are not automatically invalidated when BPEN is cleared; the BBFI bit controls entry invalidation. BPEN operates independently of BPRED, and will be used even with a BPRED setting of 00.

Table 15-1. Branch Unit Control and Status Register (BUCSR)

Bits	Name	Description
		0 Branch target buffer prediction disabled 1 Branch target buffer prediction enabled (enables BTB to predict branches)

15.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. As many as three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

The following table shows the concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 15-2. Concurrent instruction issue capabilities

Class of instruction	Branch	Load/Store	Scalar integer	Scalar float	Special
Branch	—	yes	yes	yes	—
Load/Store	yes	—	yes	yes	—
Scalar integer	yes	yes	yes[1]	yes	—
Scalar float	yes	yes	yes[2]	—	—
Special	—	—	—	—	—

[1] Excludes multiply or divide class instructions occurring in both issue slots.

[2] Excludes divide/sqrt class instructions occurring in both issue slots

15.4 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in Table 15-3. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide instructions are not pipelined and block other instructions from executing during execution.

Timing for EFPU instructions is detailed in Table 15-6.

Timing for LSP instructions is detailed in:

- LSP simple instruction timing—Table 15-7
- LSP complex instruction timing—Table 15-8
- LSP shift/rotate instruction timing—Table 15-9
- LSP vector compare instruction timing—Table 15-10
- LSP vector select instruction timing—Table 15-11
- LSP vector data arrangement instruction timing—Table 15-12
- LSP multiply and multiply/accumulate instruction timing—Table 15-13
- LSP dot product instruction timing—Table 15-14
- LSP miscellaneous vector instruction timing—Table 15-15
- LSP load and store instruction timing—Table 15-16

Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 15-3. Instruction class cycle counts

Class of Instructions	Latency	Throughput	Special notes
integer: **add**, **sub**, **shift**, **rotate**, **logical**, **cntlzw**	1	1	—
integer: **compare**	1	1	—
Branch	3/2/1	3/2/1	Correct branch lookahead allows single-cycle execution. Worst-case mispredicted branch is 3 cycles.
multiply	2	1	—
divide	4–14	4–14	Data-dependent timing
CR logical	1	1	—
loads (non-multiple)	2	1	—
load multiple	2 + *n*/2 (max)	1 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
stores (non-multiple)	2	1	—

Bit reversed increment	**zbrminc**	1	1

Instruction timing for LSP load and store instructions instructions is shown in Table 15-16.

Table 15-16. LSP load and store instruction timing

Instruction	Latency	Throughput
all **zv** loads	—	1
all **zv** stores	—	1

15.5 Reservation instructions and cache interactions

If the CPU supports reservation instruction functionality, the CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

15.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. This register is also used by the LSP APU. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in the following figure.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0										FINXS	FINVS	FDBZS	FUNFS	FOVFS	MODE	SOV	OV	FG	FX	FINV	FDBZ	FUNF	FOVF	0	FINXE	FINVE	FDBZE	FUNFE	FOVFE	FRMC	

SPR - 512; Read/Write; Reset - 0x0

Figure 15-6. LSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 15-17. LSP/EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z4251n3 Supports only mode 0.

Table continues on the next page...

Table 15-17. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
		Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by e200 core)
16 (48)	SOV	Summary integer overflow Defined by LSP APU.
17 (49)	OV	Integer overflow Defined by LSP APU.
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG l FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled

Table continues on the next page...

Table 15-17. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
		1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31 (62:63)	FRMC	Embedded Floating-point Rounding Mode Control 00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward -Infinity

15.7 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

15.7.1 Cache overview

The e200z4251n3 processor supports an 8 KB 2-way set-associative instruction and 4KB 2-way set-associative data cache with a 32-byte line size. The caches improves system performance by providing low-latency data to the e200z4251n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z4251n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

15.7.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR0 register is shown in the following figure.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
WID		0		WDD		0						DCWA	0		DCECE	DCEI	DCLOC		0						DCEA		DCLOINV	0	DCABT	DCINV	DCE

SPR - 1010; Read/Write; Reset - 0x0

Figure 15-7. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 15-18. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills.

Table continues on the next page...

Table 15-18. L1CSR0 field descriptions (continued)

Bits	Name	Description
		1 The corresponding way in the data cache is not available for replacement by data miss line fills.
8:11	—	Reserved[1]
12	DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved[1]
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.
17:18	DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. **Note:** When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	DCEA	Data Cache Error Action

Table continues on the next page...

Table 15-18. L1CSR0 field descriptions (continued)

Bits	Name	Description
		00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses.Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

[1] These bits are not implemented and should be written with zero for future compatibility.

15.7.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR1 register is shown in the following figure.

0	ICECE	ICEI	ICLOC	0	ICEA	ICLOINV	0	ICABT	ICINV	ICE
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14	15	16	17 18	19 20 21 22 23 24	25 26	27	28	29	30	31

0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size

Table continues on the next page...

Table 15-21. L1CFG1 field descriptions (continued)

Bits	Name	Description
		00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

15.7.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

15.7.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.

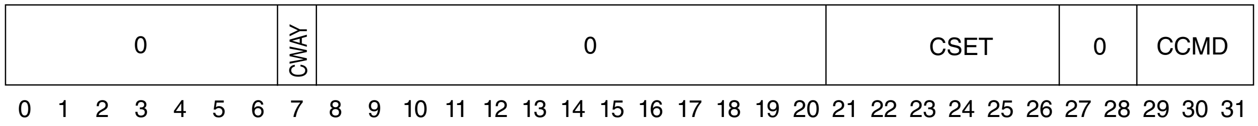
15.7.8 Cache Invalidate by Set and Way

e200z4251n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1**} instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

15.7.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in the following figure.



SPR - 1016; Read/Write; Reset - 0x0

Figure 15-11. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in the following table.

Table 15-22. L1FINV0 field descriptions

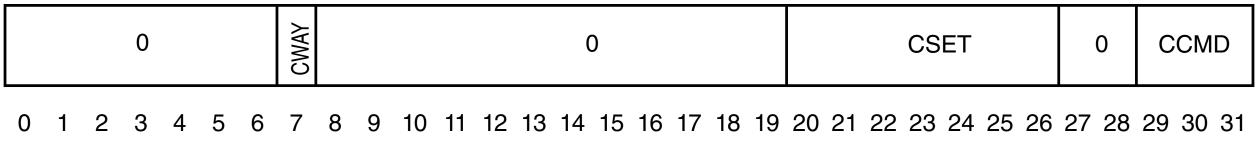
Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8: 20	—	Reserved[1] for set extension
21 :26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 = The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

[1] These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.7.8.2 L1FINV1

The L1FINV1 register is shown in following figure.



SPR - 959; Read/Write; Reset - 0x0

Figure 15-12. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 15-23. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8: 19	—	Reserved[1] for set extension
20 :26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

[1] These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.7.9 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR0[DCECE] and L1CSR1[ICECE] control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache ($L1CSR\{0,1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

15.7.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by L1CSR{0,1}$_{\text{[D,I]CLOC}}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via L1CSR{0,1} $_{\text{[D,I]CLOC}}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

15.7.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If L1CSR1$_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If L1CSR0$_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction or an L1FINV{0,1} invalidation operation.

15.8 Exceptions

Interrupts implemented in e200z4251n3 and the exception conditions that cause them are listed in the following table.

Table 15-24. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00	**p_critint_b** is asserted and MSR$_{CE}$ = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[1]	Interrupt Controller interrupt and MSR$_{EE}$ = 1

Table continues on the next page...

Table 15-24. Exceptions and Conditions (continued)

Interrupt type	Interrupt vector offset value	Causing conditions
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. LSP ld and st instructions not properly aligned 4. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/PMGC0$_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/PMGC0$_{UDI}$ = 1
EFPU Data Exception	0xA0	Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

15.8.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

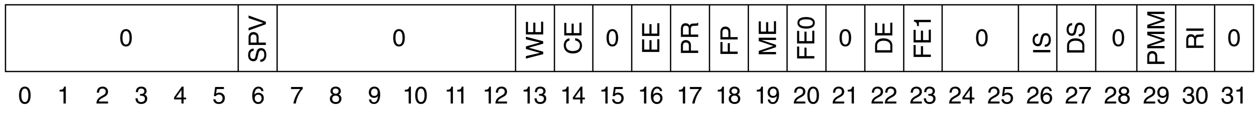
31	—	Reserved	—

15.8.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z4251n3 MSR is shown in the following figure.



Read/Write; Reset - 0x0

Figure 15-14. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 15-26. MSR field descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	SPV	SP/Embedded FP/Vector available 0 SP/Embedded FP Double/Vector unit is unavailable. The processor cannot execute SP/ Embedded FP Double or Vector Unit instructions. 1 SP/Embedded FP Double/Vector unit is available. The processor can execute SP/ Embedded FP Double or Vector Unit instructions. **NOTE:** The e200z4251n3 processor does not support these units in hardware. An Illegal Instruction exception is generated for attempted execution of these instructions regardless of the setting of SPV. SPV is ignored, but cleared on exceptions.
7:12	—	Reserved
13	WE	Wait State (Power management) enable. **NOTE:** this bit is implementation dependent and is being phased out. It will be removed in a future release. Currently it is implemented as a writeable bit, and is ignored, but cleared on exceptions.
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	FP	Floating-Point Available 0 Floating point unit is unavailable. The processor cannot execute floating-point instructions, including floating-point loads, stores, and moves. 1 Floating Point unit is available. The processor can execute floating-point instructions. **NOTE:** The e200z4251n3 processor does not support the PowerISA 2.06 floating point unit in hardware, and an Illegal Instruction exception is generated for attempted execution of PowerISA 2.06 floating point instructions regardless of the setting of FP. FP is ignored, but cleared on exceptions.
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	FE0	Floating-point exception mode 0 (not used) **NOTE:** The e200z4251n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE0 is ignored, but cleared on exceptions.

Table continues on the next page...

Table 15-26. MSR field descriptions (continued)

Bit(s)	Name	Description
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23	FE1	Floating-point exception mode 1 (not used) **NOTE:** The e200z4251n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE1 is ignored, but cleared on exceptions.
24:25	—	Reserved
26	IS	Instruction Address Space 0 The processor directs all instruction fetches to address space 0. 1 The processor directs all instruction fetches to address space 1. **NOTE:** The e200z4251n3 processor does not support Address Spaces, thus the IS bit is ignored, but cleared on exceptions.
27	DS	Data Address Space 0 The processor directs all data storage accesses to address space 0. 1 The processor directs all data storage accesses to address space 1. **NOTE:** The e200z4251n3 processor does not support Address Spaces, thus the DS bit is ignored, but cleared on exceptions.
28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

15.8.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

MCP	IC_DPERR	0	DC_DPERR	EXCP_ERR	IC_TPERR	DC_TPERR	IC_LKERR	DC_LKERR	0		NMI	MAV	MEA	U	IF	LD	ST	G	0		STACK_ERR	IMEM_PERR	DMEM_RDPERR	DMEM_WRPERR	0		BUS_IRERR	BUS_DRERR	BUS_WRERR	BUS_WRDSI	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 572; Read/Clear; Reset - 0x0

Figure 15-15. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling $\mathrm{MSR}_{\mathrm{ME}}$ to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $\mathrm{MSR}_{\mathrm{ME}} = 1$.

Table 15-27. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid	Status	—

Table continues on the next page...

Table 15-27. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition		
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[2]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR[3]	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error	Async Mchk	Maybe

Table continues on the next page...

Table 15-27. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates an uncorrectable error in the DMEM on a CPU port write access.		
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
   - "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
2. Note that since no address translation mechanism is present on e200z4251n3, the MEA value is always set to '0'.
3. Will not be set by e200z4251n3 since no local instruction memory is present.

15.8.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

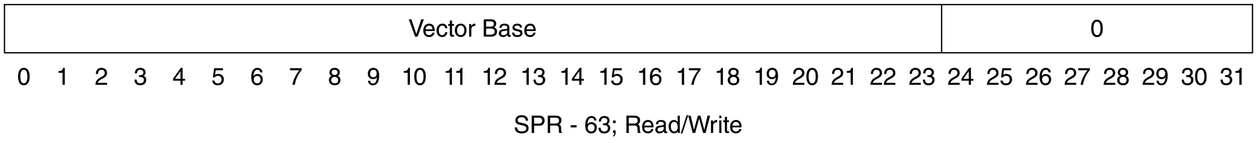


Figure 15-16. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 15-28. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256-byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.8.5 Interrupt Definitions

15.8.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 15-29. Critical Input Interrupt—register settings

<table>
<tr><th>Register</th><th colspan="6">Setting description</th></tr>
<tr><td>CSRR0</td><td colspan="6">Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.</td></tr>
<tr><td>CSRR1</td><td colspan="6">Set to the contents of the MSR at the time of the interrupt</td></tr>
<tr><td rowspan="5">MSR</td><td>SPV</td><td>0</td><td>FP</td><td>0</td><td>FE1</td><td>0</td></tr>
<tr><td>WE</td><td>0</td><td>ME</td><td>—</td><td>IS</td><td>0</td></tr>
<tr><td>CE</td><td>0</td><td>FE0</td><td>0</td><td>DS</td><td>0</td></tr>
<tr><td>EE</td><td>0</td><td>DE</td><td>—/0[1]</td><td>PMM</td><td>0</td></tr>
<tr><td>PR</td><td>0</td><td></td><td></td><td>RI</td><td>—</td></tr>
<tr><td>ESR</td><td colspan="6">Unchanged</td></tr>
<tr><td>MCSR</td><td colspan="6">Unchanged</td></tr>
<tr><td>DEAR</td><td colspan="6">Unchanged</td></tr>
<tr><td>Vector</td><td colspan="6">$IVPR_{0:23}$ || 0x00 (autovectored)
$IVPR_{0:15}$ || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)</td></tr>
</table>

[1] Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

15.8.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 15-30. Machine Check Interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	$IVPR_{0:23}$ || 0x10					

[1] Clearing of DE is optionally supported by control in HID0.

15.8.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 15-31. Data Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.					
Vector	IVPR$_{0:23}$ || 0x20					

15.8.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

The following table lists register settings when an ISI is taken.

Table 15-32. Instruction Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	IVPR$_{0:23}$ || 0x30					

15.8.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 15-33. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x40 (autovectored) IVPR0:15 || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

15.8.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.
- Execution of an LSP APU load or store instruction that is not properly aligned.

The following table lists register settings when an alignment interrupt is taken.

Table 15-34. Alignment Interrupt—register settings

<table>
<tr><th>Register</th><th colspan="6">Setting description</th></tr>
<tr><td>SRR0</td><td colspan="6">Set to the effective address of the excepting load/store/dcbz instruction.</td></tr>
<tr><td>SRR1</td><td colspan="6">Set to the contents of the MSR at the time of the interrupt</td></tr>
<tr><td rowspan="5">MSR</td><td>SPV</td><td>0</td><td>FP</td><td>0</td><td>FE1</td><td>0</td></tr>
<tr><td>WE</td><td>0</td><td>ME</td><td>—</td><td>IS</td><td>0</td></tr>

<tr><td>Vector</td><td colspan="6">IVPR$_{0:23}$ || 0x50</td></tr>
</table>

15.8.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z4251n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z4251n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR$_{PR}$ = 1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with SPRN$_5$ = 1 (even if the SPR is undefined)

The e200z4251n3 will invoke a Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *Power ISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 15-35. Program Interrupt—register settings

Register	Setting description

15.8.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- $PMLCa x_{CE}$ = 11; that is, for the given counter the overflow condition is enabled.
- $PMC x_{OV}$ = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 15-36. Performance Monitor Interrupt—Register Settings

Register	Setting description					
SRR0/ DSRR0	Set to the effective address of the next instruction to be executed.					
SRR1/ DSRR1[1]	Set to the contents of the MSR at the time of the interrupt.

DEAR	Unchanged					
Vector	$\text{IVPR}_{0:23}$ || 0xB0					

15.8.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

15.9 Memory Protection Unit (MPU)

15.9.1 MPU Overview

The e200z4251n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

15.9.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

15.9.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure

31	1	///	1 1 1 0 1 1 0 0 1 0	/
0 5	6	7 20	21 30	31

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

15.9.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe

31	1	///	1 1 1 1 0 1 0 0 1 0	/
0 5	6	7 20	21 30	31

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

15.9.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the core.

mpusync　　mpusync

MPU Synchronize

15.9.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z4251n3 MPU design. The MMUCFG register is shown in the following figure.

0	RASIZE	0	PIDSIZE	NMPUS	NTLBS	MAVN
0 1 2 3 4 5 6 7	8 9 10 11 12 13 14	15 16 17 18 19 20	21 22 23 24 25	26 27	28 29	30 31

SPR - 1015; Read-Only

Figure 15-17. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in the following table.

Table 15-42. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU

Table continues on the next page...

Table 15-42. MMUCFG field descriptions (continued)

Bits	Name	Function
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

15.9.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z4251n3 MPU. The MPU0CFG register is shown in following figure.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 692; Read-Only

Figure 15-18. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in the following table.

Table 15-43. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved

Table continues on the next page...

Table 15-43. MPU0CFG field descriptions (continued)

Bits	Name	Function
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

15.9.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in the following figure.

0																BYPSR	BYPSW	BYPSX	BYPUR	BYPUW	BYPUX	0		DRDEN	DWDEN	IDEN	0	TIDCTL	0	MPUFI	MPUEN
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 1014; Read/ Write; Reset - 0x0[1]

Figure 15-19. MPU0 Control and Status Register 0 (MPU0CSR0)

Note

[1] Reset by processor reset **p_reset_b** if EDBCR0$_{EDM}$ = 0, as well as unconditionally by an internal power-on reset signal. If EDBCR0$_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in the following table.

Table 15-44. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved

Table continues on the next page...

Table 15-44. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accessesThis bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved

Table continues on the next page...

Table 15-44. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable

Table 15-44. MPU0CSR0 field descriptions

Bits	Name	Description
		This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

15.9.9 MPU Assist Registers (MAS)

The core uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in Figure 15-20. Fields are defined in Table 15-45.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
VALID	IPROT	SEL		0	RO	DEBUG	INST	SHD	0			ESEL				0	UAMSK			UW	SW	UX/UR	SX/SR	IOVR	GOVR[1]	1	1	I	0	G[1]	0

SPR - 624; Read/ Write; Reset - Unaffected

Figure 15-20. MPU Assist Register 0 (MAS0)

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 15-45. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 = This MPU entry is invalid 1 = This MPU entry is valid
1	IPROT	Invalidation Protect 0 = Entry is not protected from invalidation 1 = Entry is protected from invalidation
2:3	SEL	Selects MPU for access: 00 = Reserved, no access 01 = Reserved, no access

Table continues on the next page...

Table 15-45. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		10 = Select MPU 11 = Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 = This MPU entry is writable 1 = This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 = This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 = This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 = This MPU entry is used for matching data accesses only 1 = This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 = The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 = The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12 :15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved
17:19	UAMSK	Upper Address Mask Control

Table continues on the next page...

Table 15-45. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 = No upper address bits are masked, address matching uses all 32 address bits for accesses 001 = The most significant access address bit is forced to zero before matching 010 = The two most significant access address bits are forced to zero before matching 011 = The three most significant access address bits are forced to 0 before matching 100 = The four most significant access address bits are forced to 0 before matching 101 = The upper five access address bits are forced to zero before matching 11x = Reserved, do not use
20	UW	User Mode Write PermissionDetermines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No User mode Write permission 1 = User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No Supervisor mode Write permission 1 = Supervisor mode has Write permission
22	UX/UR	User Mode Execute / Read Permission Determines User mode Execute (X) permission when INST = 1, or User mode Read (R) permission when INST = 0. 0 = No User mode Execute/ Read permission 1 = User mode has Execute/ Read permission
23	SX/SR	Supervisor Mode Execute / Read Permission Determines Supervisor mode Execute (X) permission when INST = 1, or Supervisor mode Read (R) permission when INST = 0. 0 = No Supervisor mode Execute/ Read permission 1 = Supervisor mode has Execute/ Read permission
24	IOVR	Cache-Inhibit attribute OverrideDetermines whether this matching entry overrides the I bit settings of other matching entries and the cache-inhibited region configuration signals 0 = No override of I attribute by entry 1 = Entry I bit overrides I attribute
25	GOVR/—	G attribute Override Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = No override of G attribute by entry 1 = Entry G bit overrides G attribute

Table continues on the next page...

Table 15-45. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
26	—	Reserved
27	—	Reserved
28	I	Cache Inhibited This attribute may be overridden by the cache-inhibited region configuration input settings. When the core memory protection unit (CMPU) is disabled, the CMPU configuration is ignored and this bit is ignored also. 0 = This region is considered cacheable 1 = This region is considered cache-inhibited
29	—	Reserved
30	G/—	Guarded This attribute may be overridden by the guarded region configuration input settings.This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 = All loads and stores to this region are performed without speculation (i.e. they are known to be required)
31	—	Reserved

The MAS1 register is shown in Figure 15-21. Fields are defined in Table 15-46.

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

15.10 Local memories

15.10.1 Local Data memory overview

Local Data (DMEM) memory has been added to provide low latency access for critical instruction routines and data operands. Access latency (zero wait-states) is similar to that of a data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity tightly coupled storage.

The local memory has one dedicated port for CPU accesses and another shared slave port for external accesses. DMEM provides a dedicated port to the CPU's load/store unit. Access via the dedicated CPU port is referred to as *front door* access. Access via the slave port is referred to as *back door* access.

Local memory occupies a portion of the processor's address space and is conditionally accessed in parallel with the corresponding cache (if present) when a CPU request is made, based on an address decode comparison early in the access pipeline.

External masters use the shared slave port, which is implemented as an AHB 2.v6 slave interface, to access the DMEM. Slave port accesses are arbitrated with the CPU port in a round-robin fashion to prevent starvation from occurring on either port.

NOTE

DMEM, by default, is always accessed through the front door (CPU) interface, regardless of whether the program uses Decorated Access, Non-decorated Cache Bypass, Atomic Load and Reserve instructions, as well as regular load/store instructions (stw, lwz, for example). The only exception is when the core's DMEMCTL0 register is set to bypass the type of DMEM access used onto AHB back door slave interface. Regular load/store instructions always access DMEM through the front door interface since no bypass control is available for these kinds of instructions.

15.10.2 Local memory control and configuration

DMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.10.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z4251n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in the following figure.

DMEM BASE ADDR	0	DECUA	DECA	0	DMSIZE	0
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19	20	21	22	23	24 25 26 27 28 29	30 31
CURRENT DMEM BASE ADDRESS VALUE	0	1	1	0	010000 (64 KB)	00

SPR - 694; Read-only; Privileged

Figure 15-25. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in the following table.

Table 15-49. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB.
30:31	—	Reserved

15.10.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DCR - 496; Read/Write; Reset[1] - 19‘b0 || p_dmem_rstcfg[8,6:7,0] || 4‘b0 || p_dmem_rstcfg[1:5]; Privileged

Figure 15-26. DMEM Control Register 0 (DMEMCTL0)

Note

[1] Reset by an internal power-on reset signal or by an internal destructive reset signal. Unaffected by **p_reset_b**.

Table 15-50. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASEADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16 :18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[8]** input, which is internally hard coded.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.

Table continues on the next page...

Table 15-50. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		Note: This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[6]** input, which is internally hard coded.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[7]** input, which is internally hard coded.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[0]** input which is internally hard coded.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits.
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set.

Table continues on the next page...

Table 15-50. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the values of the **p_dmem_rstcfg[1:2]** inputs, which are internally hard coded.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[3]** input, which is an internally hardcoded signal.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[4]** input, which is internally hard coded.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written.

Table 15-50. DMEMCTL0 field descriptions

Bits	Name	Description
		1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[5]** input, which is an internally hard coded signal.

15.10.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed. All other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in $\text{DMEMCTL0}_{\text{DBYPCB, DBYPATF, DBYPDEC}}$.

15.11 End-to-End ECC Support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

15.11.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

15.11.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0																												IDAC	IECCEN	DDAC	DECCEN

DCR - 510; Read/Write; Reset - 0x5 || p_e2e_rstcfg[0:3]; Privileged

Figure 15-28. e2eECC Control Register 0 (E2ECTL0)

Table 15-52. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices.

Table 15-52. E2ECTL0 field descriptions

Bits	Name	Description
		1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $\text{E2ECTL0}_{\text{[I,D]ECCEN}}$ control bits.

The $\text{E2ECTL0}_{\text{[I,D]DAC}}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.11.1.2 End-to-End ECC fault injection by software

Fault injection provides a way to test error recovery and portions of the error detection/ correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits). For the case of an external read access that receives an ERROR response (HRESP=ERR), the RCHKBIT field is written with all zeros.

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 15-29. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 15-53. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked). If the CPU receives an ERROR response (HRESP=ERR) on an external read access, the RCHKBIT field is written with all zeros.
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation.

Table continues on the next page...

Table 15-53. E2EECSR0 field descriptions (continued)

Bits	Name	Description
		10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further fault injection. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 16
System Integration Unit Lite2 (SIUL2)

16.1 Introduction

16.1.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and as many as 32 ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is that it enables the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls device I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

The external interrupt sources can be configured at the MCU level to be used with any chip pad. From 1 to 32 of the interrupt sources can be configured to have a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the REQ pins in the device packages.

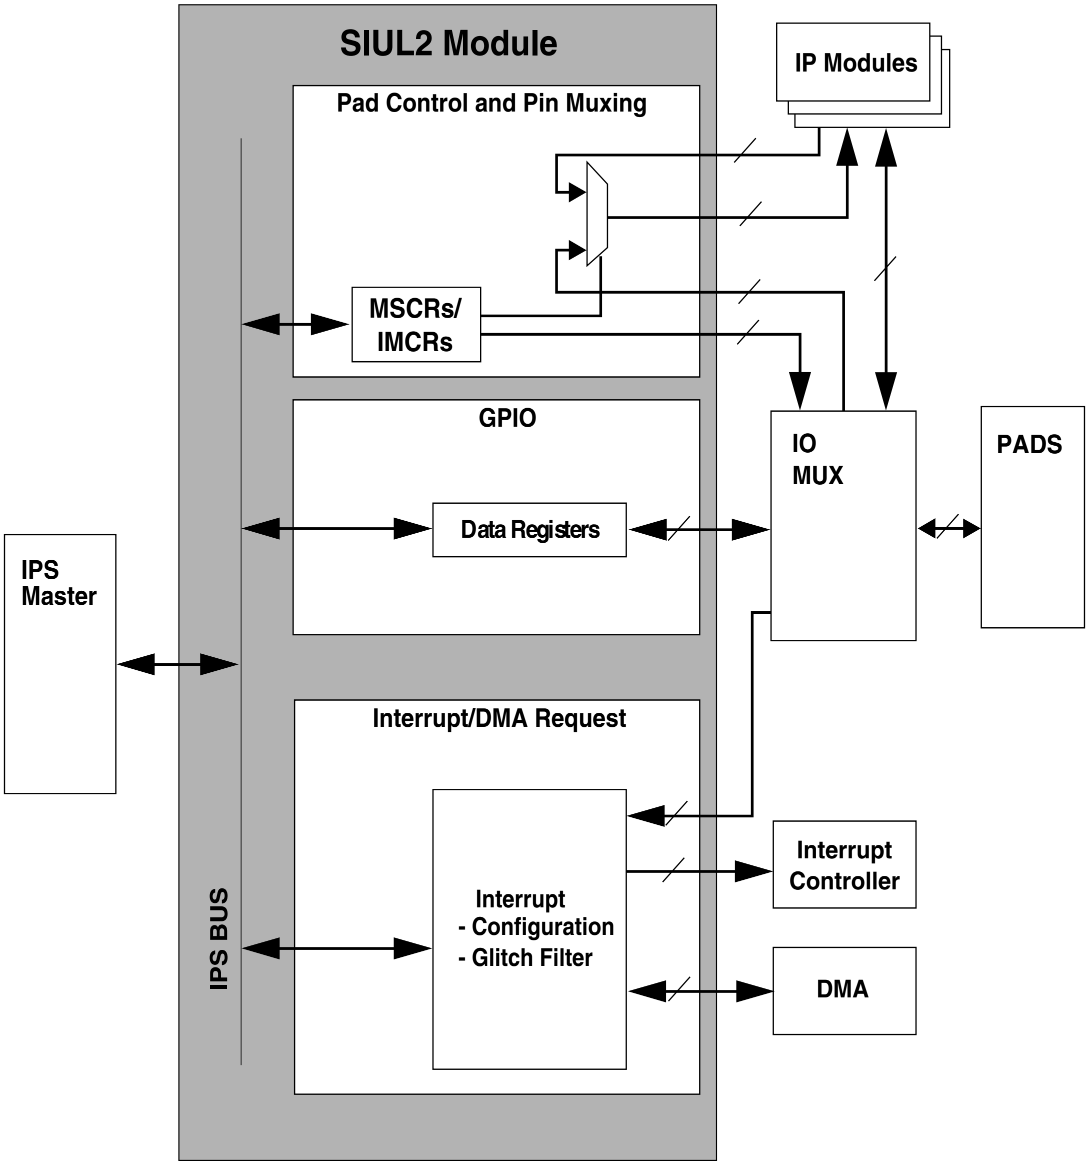

Figure 16-1. System Integration Unit Lite2 block diagram

16.1.2 Features

The System Integration Unit Lite2 supports these distinctive features:

- 1 to 32 GPIO ports with data control
    - Drive data to as many as 16 independent I/O channels
    - Sample data from as many as 16 independent I/O channels

Two 16-bit registers can be read/written with one access for a 32-bit port, if needed.

External interrupt/DMA request support with:

- 1 to 4 system interrupt vectors for 1 to 4 interrupt sources with independent interrupt masks. For 32 external interrupt sources (REQ pins), four groups have eight interrupt sources each, and each of the four groups is assigned one system interrupt vector.
- 1 to 32 programmable digital glitch filters, one for each REQ pin
- 1 to 4 system DMA request channels for 1 to 4 REQ pins
- Edge detection

Additionally the SIUL2 contains the Multiplexed Signal Configuration Registers (MSCR) that configure the electrical parameters and settings for as many as 512 functional pads. The number of these registers that is actually implemented varies by device. These registers configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control
- Hysteresis control
- Internal pull control and pull selection
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration

16.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0)
- SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0 (SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0 to SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 Multiplexed Single Configuration Register (SIUL2_MSCR0 to SIUL2_MSCR511 and SIUL2_IMCR0 to SIUL2_IMCR511): Only the specific MSCRs and IMCRs that are actually implemented on a device are protected.

A compiled list identifies the protected registers at specific addresses for this device.

16.2 Memory map and register description

This section provides a detailed description of all registers accessible in the SIUL2 module in address order. Each description includes a standard register diagram. Details of register bit and field function follow the register diagrams, in bit order.

The following table lists the implemented SIUL2 registers.

NOTE

> Undocumented register spaces in the SIUL2 memory map, including addresses shown as "blank," are reserved. Reserved registers read as 0, and writes to these registers have no effect. If supported and enabled by the MCU, a transfer error is issued for attempts to access a completely reserved register space unless it is an 8 bit access. Do not expect transfer errors on 8 bit

accesses to reserved register space. A write to a reserved register bit has no effect.

16.2.1 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)

This register holds identification information about the device.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

NOTE

See the chip-specific SIUL2 information for this register's reset value.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	PARTNUM															
W																
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

Reset	0	*	*	*	*	*	0	0	*	*	*	*	*	*	*	*

* Notes:
- MINOR_MASK field: Value is set at the factory and increments with each revision of the device.
- MAJOR_MASK field: Value is set at factory and increments with each revision of the device.
- PKG field: Values are set at factory and cannot be modified.
- PARTNUM field: Value is set at factory and cannot be changed.

SIUL2_MIDR1 field descriptions

Field	Description
0–15 PARTNUM	MCU Part Number For the full part number this field must be combined with MIDR2.PARTNUM[23:16]

Table continues on the next page...

SIUL2_MIDR1 field descriptions (continued)

Field	Description
16 ED	Always reads 0.
17–21 PKG	Package Settings This field can by read by software to determine the package type that is used for the particular device: 0b01101: 144-pin QFP 0b10000: 208-ball BGA All other bit combinations are reserved.
22–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 MAJOR_MASK	Major Mask Revision
28–31 MINOR_MASK	Minor Mask Revision

16.2.2 SIUL2 MCU ID Register #2 (SIUL2_MIDR2)

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

NOTE

See the chip-specific SIUL2 information for this register's reset value.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- PARTNUM field: Value is set at factory and cannot be changed.
- FLASH_SIZE_2 field: Value is set at factory and cannot be changed.
- FLASH_SIZE_1 field: Value is set at factory and cannot be changed.

SIUL2_MIDR2 field descriptions

Field	Description
0 SF	Manufacturer 0 Freescale Semiconductor, Inc. 1 Reserved
1–4 FLASH_SIZE_1	Coarse granularity for flash memory size The value of this field needs to be combined with the value of the FLASH_SIZE_2 field to calculate the actual memory size. 0b0110: 1 MB 0b0111: 2 MB This value is set at the factory and cannot be changed. Other values are reserved.
5–8 FLASH_SIZE_2	Fine granularity for flash memory size The value of this field needs to be combined with the value of the FLASH_SIZE_1 field to calculate the actual memory size. 0b0000: 0 x (FLASH_SIZE_1 / 8) 0b0010: 2 x (FLASH_SIZE_1 / 8) 0b0100: 4 x (FLASH_SIZE_1 / 8) This value is set at the factory and cannot be changed.
9–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 PARTNUM	ASCII character in MCU Part Number This field specifies the part number suffix, and needs to be combined with MIDR1[PARTNUM] to provide the full chip number. 0x50 P This value is set at the factory and cannot be changed. All other values are reserved.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

16.2.3 SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set regardless of the state of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) - Standard. The IRQ Flag bit remains set until cleared by software or through the servicing of a DMA request. The IRQ Flag bits are cleared by writing a '1' to the bits. A write of '0' has no effect. The number of bits implemented is specified by the parameter that defines the number external IRQ pins.

This register supports 8-, 16-, and 32-bit accesses.

16.2.4 SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0). The number of bits implemented is specified by the parameter that defines the number of external IRQ pins. This register is used to enable the interrupt messaging to the interrupt controller.

This register supports 8-, 16-, and 32-bit accesses.

16.2.5 SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. The number of bits implemented is specified by the parameter that defines the number of DMA request outputs.

This register supports 8-, 16-, and 32-bit accesses.

16.2.7 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)

This register is used to enable falling-edge triggered events on the corresponding interrupt pads.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

If both the IREE it and IFEE bits are cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

Address: 0h base + 30h offset = 30h

16.2.8 SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)

This register is used to enable a digital filter counter on the corresponding interrupt pads to filter out glitches on the inputs. The number of interrupts supporting this feature is MCU dependent and can be configured between 1 and 32.

This register supports 8-, 16-, and 32-bit accesses.

Address: 0h base + 38h offset = 38h

16.2.9 SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR*n*)

These registers are used to configure the filter counter associated with each digital glitch filter.

NOTE

> These registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Address: 0h base + 40h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																												MAXCNT

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIUL2_IFMCR*n* field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MAXCNT	Maximum Interrupt Filter Counter setting MAXCNT can be 0d to 15d. • For a MAXCNT value of 0d, 1d, or 2d, the filter behaves as an ALL PASS filter. • For a MAXCNT value of 3d to 15d, the filter period is TCK*MAXCNT+n*TCK, where n is 0, 1, 2, 3, or 4. TCK is the prescaled filter clock period, which is the IRC clock prescaled to the IFCP value, which is specified in SIUL2_IFCPR. TIRC is the basic filter clock period: 62.5 ns (f = 16 MHz). **NOTE:** The filter delay is 2 TCK clock cycles more than the filter period. In general, TFILTER and TDELAY are not integer multiples of TCK because DIN is asynchronous whereas DOUT is synchronous with respect to the CK clock. The factor n accounts for this uncertainty in filter period calculation.

16.2.10 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register is used to configure a clock prescaler which is used to select the clock for all digital filters. A prescaler is applied to the input clock to the SIUL2, which is the system AIPS clock counter in the SIUL2.

NOTE

> This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIUL2_IFCPR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15

16.2.11 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)

These registers select which source signal is connected to the register's associated destination, which is a chip pin that is or can be configured as an output.

For the associated chip-pin destination, the register also specifies the pin's electrical properties.

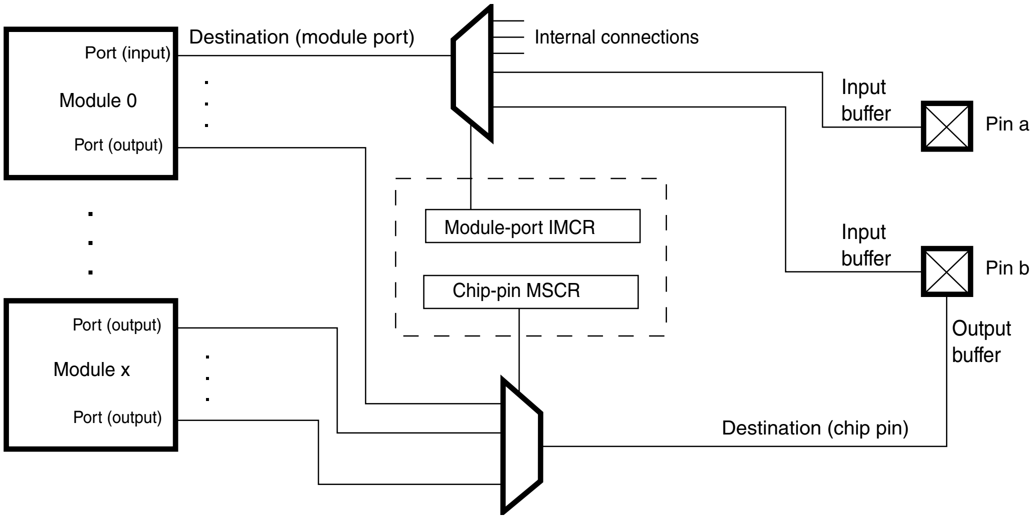

Figure 16-2. MSCR pin connection

The fields in an MSCR vary depending on its associated destination (chip pin).

For chip-pin MSCR assignments, pin types, APC support, and SSS values, see the pin-description table for your chip.

NOTE

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

Address: 0h base + 240h offset + (4d × i), where i=0d to 154d

SIUL2_MSCR*n* field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 SRC[1:0]	Slew Rate Control Used only when the associated destination is a chip pin. 00 Half drive strength with slew rate control 01 Full drive strength with slew rate control 10 Half drive strength without slew rate control 11 Full drive strength without slew rate control
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 OBE	GPIO Output Buffer Enable Applies only to digital pins. Otherwise this bit is reserved. 0 Output driver disabled 1 Output driver enabled
7 ODE	Open Drain Enable **NOTE:** To enable open drain both OBE and ODE bits need to be set. 0 Open drain function disabled 1 Open drain function enabled when OBE is also 1
8 SMC	Safe Mode Control Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control Used only when the associated destination is a chip pin that supports analog I/O. Enables the pin's analog-input-path switch.

Table continues on the next page...

SIUL2_MSCR*n* field descriptions (continued)

Field	Description
	0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 IBE	Input Buffer Enable Used only when the associated destination is a chip pin. Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis Used only when the associated destination is a chip pin. Enables input hysteresis for the associated pin. 0 Disabled 1 Enabled
14 PUS	Pull Select Determines whether the pull function is a pullup or pulldown when the pull function is enabled by the PUE field. Used only when the associated destination is a chip pin. 0 Pulldown 1 Pullup
15 PUE	Pull Enable Enables the pull function. Used only when the associated destination is a chip pin. 0 Disabled 1 Enabled
16 INV	Invert Inverts the signal selected by SSS before transmitting it to the associated destination (chip pin or module port). 0 Don't invert 1 Invert
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin). This field has a variable width depending on the number of alternate functions available for that pin. For a chip pin, the source signals are outputs from module ports.

16.2.12 SIUL2 Input Multiplexed Signal Configuration Register (SIUL2_IMCR*n*)

Selects which source signal is connected to the register's associated destination, which is an internal module port that is or can be configured as an input.

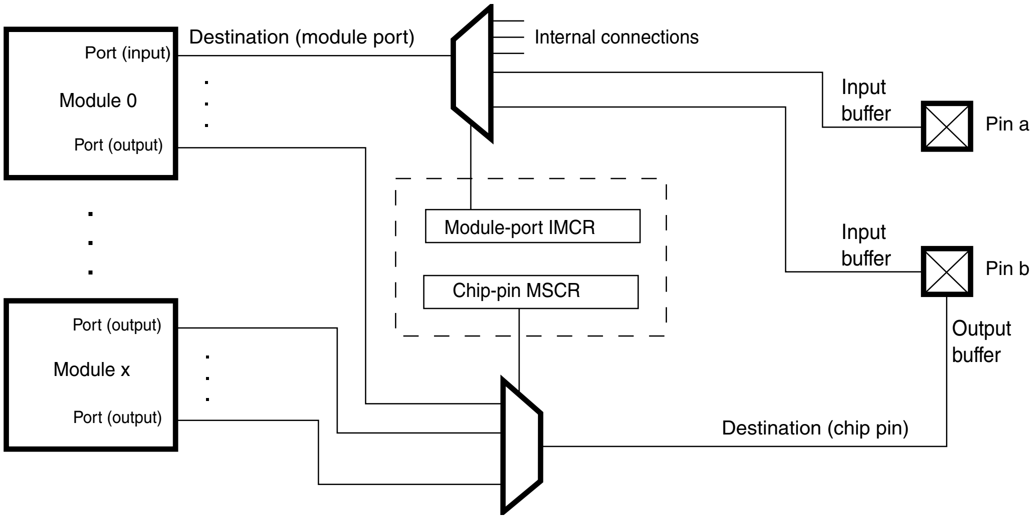

Figure 16-3. IMCR module-port connection

The fields in an IMCR vary depending on its associated destination (module port).

For IMCR assignments and SSS values, see the pin-description table for your chip.

NOTE

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

Address: 0h base + AC0h offset + (4d × i), where i=0d to 201d

31 PDI_4n3	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n3 represents PDI[4n+3], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n3 represents PDI15. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

16.2.15 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write.

The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

These registers support 8-, 16-, and 32-bit accesses.

Address: 0h base + 1700h offset + (2d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIUL2_PGPDO*n* field descriptions

Field	Description
0–15 PPDO	Parallel Pad Data Out Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO).The x and bit index define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

16.2.16 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration.The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read.

These registers support 8-, 16-, and 32-bit accesses.

Address: 0h base + 1740h offset + (2d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIUL2_PGPDI*n* field descriptions

Field	Description
0–15 PPDI	Parallel Pad Data In Reads the current pad value. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Input Registers (SIUL2_GPDI). The x and bit index define which PPDI register bit is equivalent to which PDI register bit according to the following equation: PPDI[x][y] = PDI[(x*16)+y]

16.2.17 SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO*n*)

This register can be used to selectively modify the pad values associated to PPDO[x] [0:15]. The MPGPDO[x] register may only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error response by the module. Read access will return 0.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

Address: 0h base + 1780h offset + (4d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–15 MASK	Mask Field Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0b The associated bit value in the MPPDO[x] field is ignored 1b The associated bit value in the MPPDO[x] field is written
16–31 MPPDO	Masked Parallel Pad Data Out Write the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO).The x and bit index define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: MPPDO[x][y] = PDO[(x*16)+y]

16.3 Functional description

16.3.1 General

This section provides a complete functional description of the System Integration Unit Lite2.

16.3.2 Pad Control

The SIUL2 is capable of controlling the electrical characteristics of as many as 512 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features are supported on all devices or on all pads. Support is dependent on the specific application needs and the pads implemented on the device.

The required controls are:

- Slew rate control
  - Offers improved EMC performance
  - Support for a fast and a slow slew rate
- Drive strength control
  - Offers improved EMC performance
  - As many as four different drive strength levels can be supported.
- Pull capability
  - Offers flexibility in the device configuration and the elimination of external hardware in some cases
  - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down, or no-pull enabled
- Input and output buffer control
- Hysteresis
- Open drain
  - Needed to support different pads muxed (for example, to mux IIC with non-open drain pads)
- Pad output assignment
  - Defines which chip function has control over the output of the pad

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for you to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads' individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register, allowing simplified duplication of software for each pad with indexed changes for each pad.

16.3.3 General Purpose Input and Output pads (GPIO)

The SIUL2 allows each pad to be configured as either a General Purpose Input or Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that uses the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage as many as 512 GPIO pads organized as ports that can be accessed for data reads and writes as 8-bit, 16-bi,t or 32-bit.

As shown in the following figure, all port accesses are identical, with each read or write being performed only at a different location to access a different port width.

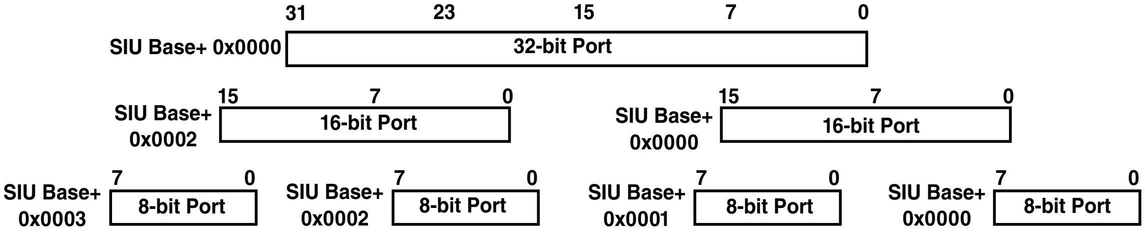

Figure 16-4. Data Port example arrangement showing configuration for different port width accesses

This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations.

The data input registers support read access only.

When a pad is configured to use one of its alternate functions, the data input values reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until re-configured to GPIO. All general purpose pads are implemented as bidirectional.

Note

In case the bi-directional operation impacts performance (for example, ADC accuracy) or is not required for a specific pad function, you can limit the functionality of the pad to "Input Only."

16.3.4 External interrupts/DMA requests (REQ Pins)

The SIUL2 supports 1 to 32 external interrupts, which can be allocated to any pad necessary at the MCU level. This allocation is fixed per MCU.

For the assignments of the external interrupts, see the Signal Description details.

The SIUL2 supports one to four interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support as many as eight external interrupt sources from the device pads.

For devices with a number of interrupt sources that is smaller than the maximum number, the MCU can implement either all four interrupt vectors with fewer sources or reduce the number of vectors as the number of sources are reduced. The following figure shows two sample scenarios.

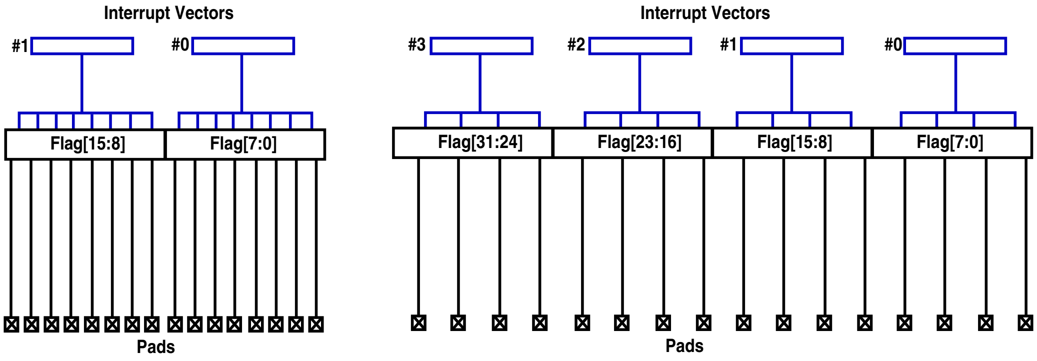

Figure 16-5. Example of different interrupt to vector mapping at MCU level

All the external interrupt pads within a single group (maximum of eight pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for the application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have digital glitch filters applied to them. The supported range is 1 to 32. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on an interrupt line.

16.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization, the user must do the following:

- Mask interrupts by clearing the EIRE*n* bits in DIRER0
- Select the pin polarity by setting the appropriate IREE*n* bits in IREER0 and the appropriate IFEE*n* bits in IFEER0 as desired
- Configure the appropriate bits in the MSCR[0:511] register for the external interrupt pin(s) desired as follows:
  - Clear the OBE and ODE bits to disable output
  - Set the IBE bit to enable the pin's input buffer
  - If using the internal pullup/pulldown, configure the appropriate PUE and PUS fields

Note

> MSCR[SSS] bits do not need to be changed for either MSCR[0:511] or IMCR[0:511] because the external interrupt pin input is directly connected to the SIUL for EIRQ pins.
>
> External interrupt pins should never be configured as outputs (MSCR[ODC] bits are not zeros) when external interrupt inputs are desired because false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRS*n* bits in DIRSR0
- Select the desired glitch filter setup for the pins by writing the following:
  - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMC*n* register for the respective external interrupt that is being used

  - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register
  - Enable the glitch filter for the desired external interrupt pins by setting the appropriate IFE*n* bits in IFER0
- Write to EIF*n* bits in DISR0 to as desired to clear any flags
- Enable the interrupt pins by setting the appropriate EIRE*n* bits in DIRER0

16.3.4.2 External interrupt management

The user can enable or disable each interrupt independently using a single rolled up register, SIUL2_DIRER0.

A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled is reserved and should not be configured. The user controls the active IRQ edge through the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

Refer to the following figure for an overview of the external interrupt implementation.

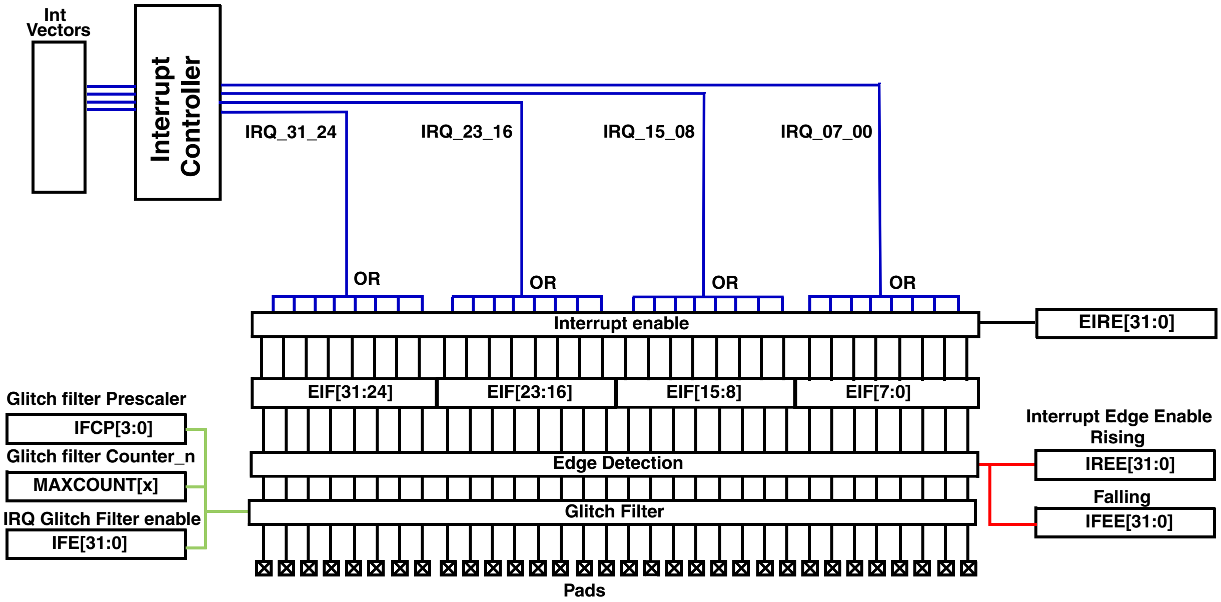

Figure 16-6. External interrupt pad diagram

16.3.4.3 External interrupt request

The REQ input pins on the device are sources for interrupt or DMA requests. The system has four possible interrupt vectors available for the REQ pins in the SIUL2. The mapping of 32 interrupt request sources to vectors and channels appears in the following table.

Table 16-1. Interrupt source mapping to SIUL2 Interrupt request output for 32 interrupt sources

Vector/Channel #	Interrupt vector source
0	REQ[07] I REQ[06] I REQ[05] I REQ[04] I REQ[03] I REQ[02] I REQ[01] I REQ[00]
1	REQ[15] I REQ[14] I REQ[13] I REQ[12] I REQ[11] I REQ[10] I REQ[09] I REQ[08]
2	REQ[23] I REQ[22] I REQ[21] I REQ[20] I REQ[19] I REQ[18] I REQ[17] I REQ[16]
3	REQ[31] I REQ[30] I REQ[29] I REQ[28] I REQ[27] I REQ[26] I REQ[25] I REQ[24]

16.3.4.4 DMA requests

The REQ pins on the device map to independent DMA request channels in the DMA controller. The maximum four pins map corresponding to four DMA request channels. See the DMA request mapping details in the Device Configuration information.

Chapter 17
Crossbar Switch (XBAR)

17.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

17.1.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
    - Allows concurrent accesses from different masters to different slaves
    - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 64-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support
- Dynamic master priority elevation

17.2 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

XBAR memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
700	Priority Registers Slave (XBAR_PRS7)	32	R/W	See section	17.2.1/515
710	Control Register (XBAR_CRS7)	32	R/W	See section	17.2.2/517

17.2.1 Priority Registers Slave (XBAR_PRS*n*)

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains less than five masters, values 0 to 3 are valid. Writing other values will result in an error.
- If the chip contains five or more masters, valid values are 0 to n-1, where n is the number of masters attached to the Crossbar Switch. Other values will result in an error.

NOTE

See the chip-specific crossbar information for the reset value of this register.

NOTE

On the MPC5744P, the reset value of these registers is 0x0320_0010.

28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 M0	Master 0 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.

17.2.2 Control Register (XBAR_CRS*n*)

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

NOTE

> See the chip-specific crossbar information for the reset value of this register.
>
> Not all HPE*n* fields may be active. See the chip-specific crossbar information for which masters support high priority elevation. Setting a field corresponding to a master that does not support high-priority elevation has no effect.

Address: 0h base + 10h offset + (256d × i), where i=0d to 7d

17.3 Functional Description

17.3.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS*n*[PCTL].

17.3.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

17.3.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

17.3.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 17-1. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

17.3.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

17.3.3.3 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

17.4 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

Chapter 18
Crossbar Integrity Checker (XBIC)

18.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers.

18.2 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
    - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
- Error injection for testing
    - Programmable master and slave port specifiers
    - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
    - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

18.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in the following diagram.

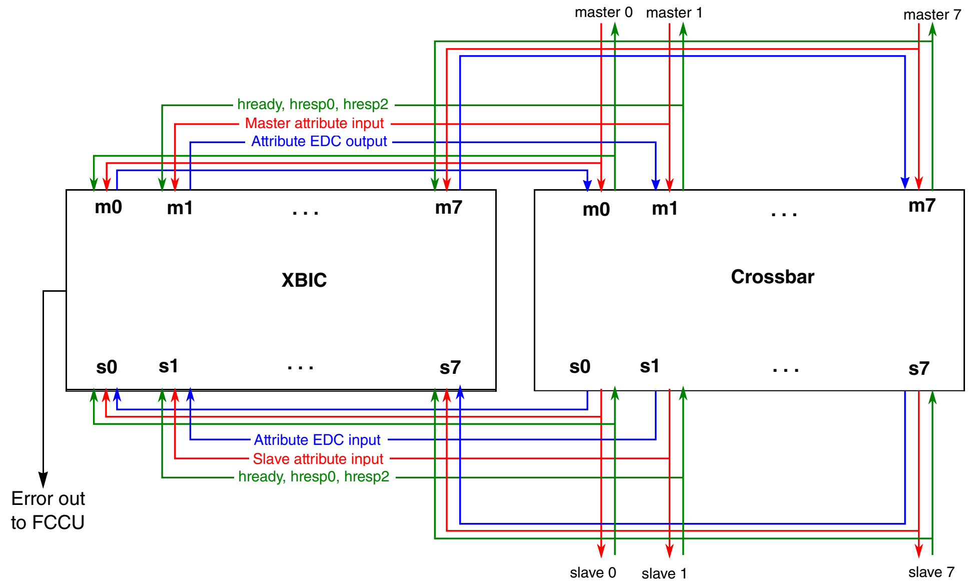

Figure 18-1. XBIC system block diagram

18.4 External signal description

The XBIC has no external interface signals.

18.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

18.5.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EIE								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0		SLV			MST						SYN				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
1–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20–23 MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24–31 SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

18.5.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the last transfer. If an attribute integrity check error was detected, the slave port, the master port, and the syndrome are captured in the SLV, MST, and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are catured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_ESR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

18.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar interface. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a individual port basis. When an error is detected, it is captured in XBIC_ESR register and XBIC also sends out an error signal to the Fault Collection and Control Unit (FCCU). Detection of an error does not generate a bus error. The XBIC integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

During the AHB address phase, the crossbar attribute information is checked using an 8-bit Error Detection Code (EDC), which detects any single- or double-bit errors. When an error is detected, due either to hardware fault or error injection, information related to the error is captured and reported in XBIC_ESR and XBIC_EAR. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in Table 18-1. Any other syndrome indicates a multi-bit error.

During the AHB data phase, the responding signals from the slave to master are checked when passing through the crossbar. When an error is detected, the information is captured in XBIC_ESR DSME0-7 field.

The XBIC can also be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared

Chapter 19
Peripheral Bridge (AIPS-Lite)

19.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

19.1.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Programming model provides memory protection functionality

19.1.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

19.2 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

19.2.1 Master Privilege Register A (AIPS_MPRA)

This register specifies eight identical 4-bit fields defining the access-privilege level associated with a bus master in the device to various peripherals. The register provides one field per bus master. Each master is assigned a logical master number. See the device configuration information for details.

Address: 0h base + 0h offset = 0h

28–31 Reserved	This field is reserved.

19.2.2 Peripheral Access Control Register (AIPS_PACR*n*)

Each of the on-platform peripherals has a 4-bit PACR *n* field, which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR *x* register.

The peripheral assignments to each PACR are defined by the memory map slot that the peripherals are assigned. See the device's memory map details for the assignments for a particular device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeroes and writes are ignored.

The following table shows the top-level structure of PACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

19.2.3 Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*)

Each of the peripherals has a 4-bit OPACR *n* field, which defines the access levels supported by this module. Eight OPACR fields are grouped together to form a 32-bit OPACR *x* register.

The peripheral assignments to each OPACR are defined by the memory map slot that the peripherals are assigned. See the device's memory map details for the assignments for a particular device. If a peripheral is absent, the corresponding OPACR field is not implemented. Reads to the location return zeroes and writes are ignored.

The following table shows the top-level structure of OPACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

29 SP7	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
30 WP7	Write Protect Determines whether the peripheral allows write accessses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
31 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

19.3 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

19.3.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only.All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

Chapter 20
System Memory Protection Unit (SMPU)

20.1 Overview

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors system bus transactions and evaluates their appropriateness using preprogrammed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

20.1.1 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The access signals coming from the crossbar switch slave ports are shown on the left. The access evaluation macros and region descriptors are in the middle, and the peripheral bus interface is on the right side.

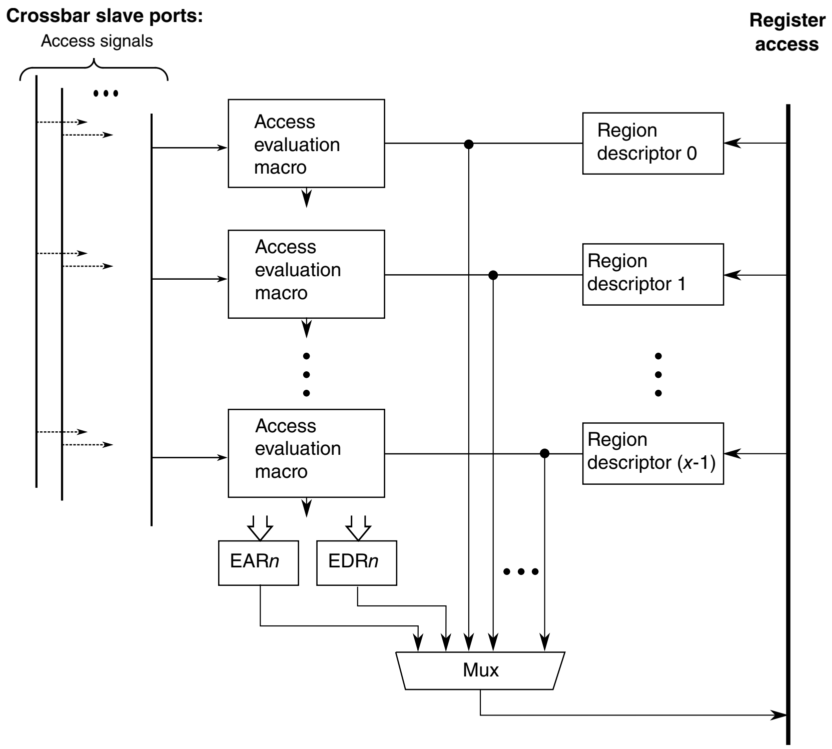

Figure 20-1. SMPU block diagram

The access evaluation macros determine hits to memory regions and detect violations to access protections. If a violation is detected, the macros update the appropriate master's error registers. For details of the access evaluation macro, see Access evaluation macro.

20.1.2 Features

The SMPU feature set includes:

- Arbitrarily sized protection regions alignable anywhere in memory.
  - Region sizes can vary from a minimum of 1 byte to a maximum of 4 GB.
- Read/write access control permissions are defined in the region descriptor.
- Global cache-inhibit attribute indicator.
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues.
- Priority given to granting permission over denying access for overlapping region descriptors.

- Detection of access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Instruction storage (ISI) or data storage (DSI) interrupts generated by aborted core accesses. Buffered writes generate Machine check exception (refer to the documentation related to the core for details).
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit.

20.2 Memory map/register definition

The programming model is partitioned into three groups:

- Control registers
- Error capture registers
- Data structure containing the region descriptors

The programming model can be referenced only in supervisor mode using 32-bit accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register, or a read of a write-only register), or in user mode generate an error termination.

NOTE

See the chip configuration details for any chip-specific register information for this module. For example, a specific instance of the module may support only eight or fewer region descriptors.

SMPU memory map

SMPU_CESR0 field descriptions

Field	Description
0–15 MERR	Master n error, where the bus master number matches the bit number Indicates a captured error in EARn and EDRn. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master n. 1 An error has occurred for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled.

20.2.2 Control/Error Status Register 1 (SMPU_CESR1)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SMPU_CESR1 field descriptions

Field	Description
0–15 MEOVR	Master n error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master n has occurred before the previous error was processed. The details of the first error are recorded in the EARn and EDRn registers and no information on subsequent errors is recorded until the associated CESR0[MERR] flag is cleared. 0 No error overrun condition has been detected for bus master n. 1 An error overrun condition has been detected for bus master n.

Table continues on the next page...

Field	Description
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. The number of region descriptors is (4 x NRGD). 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

20.2.3 Error Address Register, Bus Master n (SMPU_EAR*n*)

When the SMPU detects an access error on bus master n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0[MERR] set. Additional information about the faulting access is captured in the corresponding EDRn at the same time.[1]

Address: 0h base + 100h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SMPU_EAR*n* field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error.

[1] The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

20.2.4 Error Detail Register, Bus Master n (SMPU_EDR*n*)

When the SMPU detects an access error associated with bus master n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Information on the faulting address is captured in the corresponding EARn register at the same time. [2]

Address: 0h base + 104h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

SMPU_EDR*n* field descriptions

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDRn contains a captured error and EACD is all zeroes, the access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
25–26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference.

Table continues on the next page...

[2] The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

SMPU_EDR*n* field descriptions (continued)

Field	Description
	0 Read 1 Write
28–31 EMN	Error master number Indicates the logical bus master number of the faulting reference.

20.2.5 Region Descriptor n, Word 0 (SMPU_RGD*n*_WORD0)

The first word of the region descriptor defines the byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn_WORD3[VLD]).

Address: 0h base + 400h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SRTADDR

SMPU_RGD*n*_WORD0 field descriptions

Field	Description
0–31 SRTADDR	Start address Defines the byte start address of the memory region.

20.2.6 Region Descriptor n, Word 1 (SMPU_RGD*n*_WORD1)

The second word of the region descriptor defines the end address of the memory region. (RGDn_WORD3[VLD]).

Address: 0h base + 404h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ENDADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_RGD*n*_WORD1 field descriptions

Field	Description
0–31 ENDADDR	End address Defines the byte end address of the memory region. **NOTE:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

20.2.7 Region Descriptor n, Word 2 (SMPU_RGD*n*_WORD2)

RGD_WORD2 defines the access control rights of the memory region. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) operation.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor’s valid bit.

Address: 0h base + 408h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SMPU_RGD*n*_WORD3 field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **NOTE:** The valid bit of the RGD and the global valid bit have no effect on this bit functionality (once set, even if the RGD is not valid or SMPU is not global enabled, the RO functionality is present). 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **NOTE:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size factoring into the end address. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGDn_WORD0–2 clears this bit. 0 Region descriptor is invalid. 1 Region descriptor is valid.

20.3 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

20.3.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the connection matrix. The following block diagram represents an individual macro.

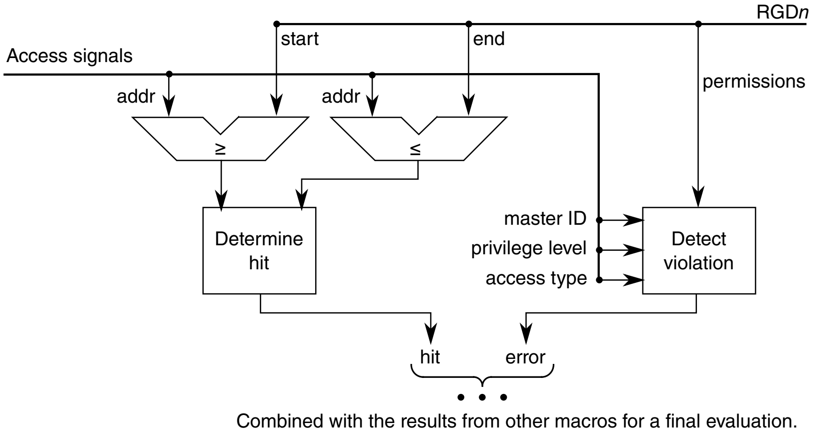

Figure 20-2. SMPU access evaluation macro

Each macro uses the information contained in the access signals (the address, the access type, and the master's ID and privilege level) and the contents of its corresponding region descriptor (RGD*n*) to perform two major functions: Hit determination and Violation determination. The individual hit and error results from each macro are then combined for a final evaluation; see Final evaluation and error terminations.

20.3.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. When RGD*n*_Word3[VLD] is 1, a region hit occurs when the requested address is between the start address (RGD*n*_Word0[SRTADDR]) and the end address (RGD*n*_Word1[ENDADDR]), inclusive.

NOTE

If ENDADDR < SRTADDR, no hit occurs.

NOTE

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

20.3.1.2 Violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master ID, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

Table 20-1. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no execute permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

20.3.2 Final evaluation and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.

3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see Application information.

NOTE

Similarly, the cache inhibit function gives a higher priority to the less restrictive result of overlapping regions. If two regions are hit and one has cache inhibit set, and the other does not, the result will not include a cache inhibit. It should also be noted that only the hit logic is taken into account for cache inhibit. For example, two region hits, one has protection violation and no cache inhibit, one has no violation and cache inhibit set. The result will be a granted access with no cache inhibit.

20.3.3 Power management

Disabling the SMPU by clearing CESR0[GVLD] minimizes power dissipation. To minimize the power dissipation of an enabled SMPU, invalidate unused region descriptors by clearing the associated RGDn_Word3[VLD] bits.

20.4 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGD*n*_Word3[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD]=0). Next, load the appropriate region descriptors (RGDn), including the setting of the RGDn_Word3[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

Note

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

20.5 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region

  Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Modifying a region descriptor

  Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word 3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Removing a region descriptor

  Clearing RGD*n*_Word3[VLD] deletes an existing region descriptor.

- Accessing the SMPU

  Allocate a region descriptor to restrict SMPU access to supervisor mode from specific masters as appropriate.

- Detecting an access error

  The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0[MERR] signals which error registers contain captured fault data. Once the error information is retrieved, write a 1 to the appropriate CESR0[MERR] bit to clear it, thereby rearming the error capture logic associated with the EAR*n* and EDR*n* registers.

- Overlapping region descriptors

Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

Chapter 21
Interrupt Controller (INTC)

21.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 32 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

21.2 Block diagram

The following figure shows the block diagram of an INTC with four processors (PRC0...PRC3). The actual number of processors is described in the chip-specific INTC information. The structure of the INTC remains the same for each implemented processor.

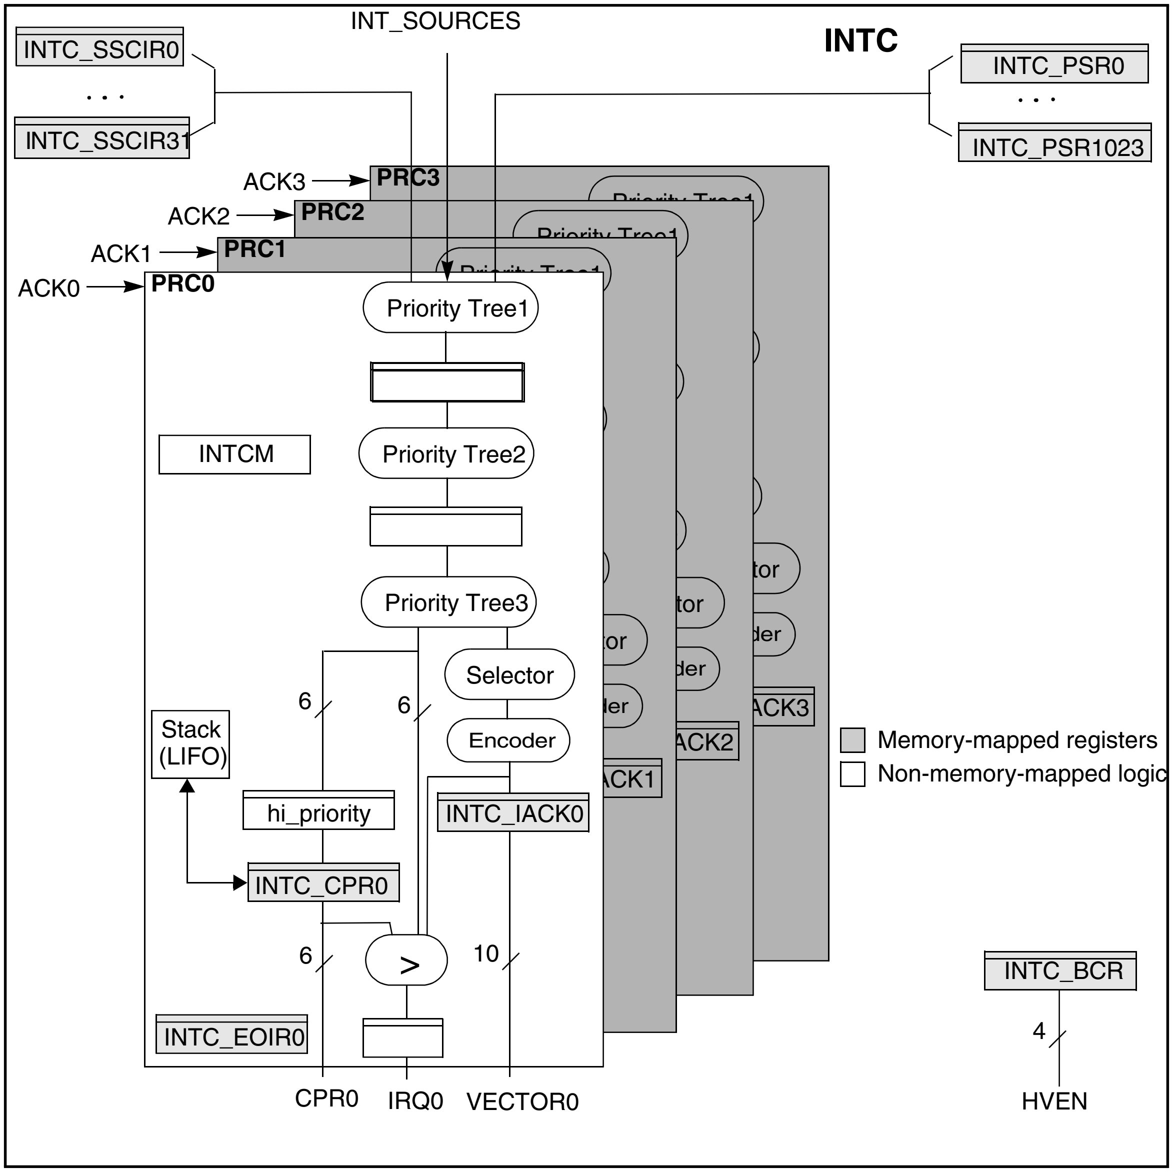

Figure 21-1. Block diagram for an INTC with four processors

21.3 Features

- Each peripheral interrupt source is software-steerable to any combination of interrupt request outputs to the following:
  - Processor 0
- 16 software-settable interrupt request sources
- 10-bit vector

    - Unique vector for each interrupt request source
    - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 32 priorities
- Each interrupt source can be triggered by software
- Preemption
    - Preemptive prioritized interrupt requests to processor
    - ISR with higher priority preempts ISRs or tasks with lower priorities
    - Automatic pushing or popping of preempted priority to or from a LIFO
    - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
    - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
    - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request
- Monitor
    - The Interrupt Controller Monitor (INTCM) provides a way to set a maximum timer count for the interrupt latency from interrupt request (IRQ) to interrupt acknowledge (IACK) or from IRQ to return from interrupt (RFI). The purpose of this function is to provide a mechanism to monitor the latency of interrupt sources for a corresponding Processor to ensure that these critical interrupts execute within the expected window of time, increasing the reliability of the device. The hardware for this function is isolated in its own hierarchy to decrease the risk of fault interference.

21.4 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

21.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN_PRCn bit in the INTC_BCR is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRC*n* bit is negated. The vector is read from the INTC_IACKRn registers. Reading the INTC_IACKR*n* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPRn onto the associated LIFO, and updates PRI in the associated INTC_CPR_PRC*n* with the new priority.

21.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVENn bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKRn, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*n* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*n* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR*n* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs is written at a time such that the PRI value in the associated INTC_CPR*n* register would need to be pushed and the previously last pushed

PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*n* is updated with the new priority, and the associated LIFO is neither pushed or popped.

21.5 Memory map and register definition

A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

With the exception of the INTC_SSCIR *n* and INTC_PSR *n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

When writing to INTC_PSRs or INTC_SSCIRs, the following restrictions (illustrated in Figure 21-2) apply:

- For PSRs, write accesses must not span 16-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).
- For SSCIRs, write accesses must not span 8-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).

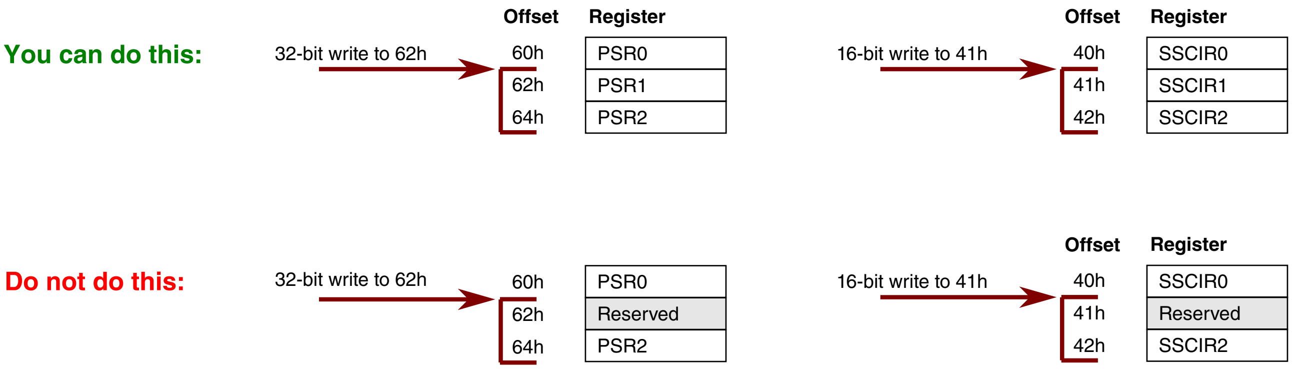

Figure 21-2. INTC_PSR*n* and INTC_SSCIR*n* write restrictions

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR *n*) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR *n*) does not affect the operation of the write.

INTC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	INTC Block Configuration Register (INTC_BCR)	32	R/W	0000_0000h	21.5.1/604

23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HVEN0	Hardware vector enable for processor 0. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode

21.5.2 INTC Current Priority Register for Processor 0 (INTC_CPR0)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 10h offset = 10h

INTC_CPR0 field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PRI	Priority of the currently executing ISR, according to the field values 31 (highest priority) down to 0 (lowest priority).

21.5.3 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_IACKR0 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.5.4 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)

Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_EOIR0 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

21.5.5 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

See Figure 21-2 for limitations on writing to this register.

Address: 0h base + 40h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read	0						0	CLR
Write							SET	w1c
Reset	0	0	0	0	0	0	0	0

INTC_SSCIR*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SET	Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
7 CLR	Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

21.5.6 INTC Priority Select Register (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32-1023, and their priorities are configured in INTC_PSR32-1023, respectively.

See Figure 21-2 for limitations on writing to this register.

NOTE

Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

NOTE

Interrupts are not detected while the PSRs are being written.

Address: 0h base + 60h offset + (2d × i), where i=0d to 1023d

Bit	0	1	2	3	4	5	6	7

Reset	0	0	0	0	0	0	0	0

INTC_PSR*n* field descriptions

Field	Description
0 PRC_SELN0	Processor select 0. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 0. 0 Interrupt request not sent to processor 0 1 Interrupt request sent to processor 0
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWTN	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SEL*n* field of the PSR.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PRIN	Priority select. Selects the priority for the interrupt requests. PRI has values 31 (highest priority) down to 0 (lowest priority).

21.5.7 INTC Monitor Mode Register 0 (INTC_MMRC0)

The Monitor Mode Register is used to configure measurement options of the INTC.

Address: 0h base + 1000h offset = 1000h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_MMRC0 field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 MM	Monitor Mode. Controls whether the INTC monitors the latency or interrupt handler time 00 Disabled 01 IACK - Interrupt Acknowledge - timer is active from assertion of IRQ until interrupt acknowledge. An error is signaled if timer exceeds the programmed interrupt latency and the programmed interrupt latency is non-zero. 10 EOI - End Of Interrupt - timer is active from assertion of IRQ until the end of the interrupt handler. The timer will continue to run even if interrupt handler is preempted. An error is signaled if timer exceeds the programmed interrupt latency and the programmed interrupt latency is non-zero. 11 SW - Software - timer is active from assertion of IRQ until the end of the interrupt handler unless it is preempted. A return from interrupt will start the timer if it is the timer associated with the active IRQ. No error is signaled; rather software can read the timer at any time.

21.5.8 INTC HIPRI Register (INTC_HIPRI*n*C0)

The HIPRI log2(SOURCES)-bit registers are used to indicate which IRQ is to be monitored or checked. The mnemonic is of the form HIPRImCn, where the 'n' is the corresponding Processor and the ‘m’ is the monitor instance for that Processor.

Address: 0h base + 1004h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_TIMER*n*C0 field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TIMER	Timer is used to count the number of INTC clock cycles up to 24 bits of resolution.

21.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

21.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI*n* value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*n*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*n* is updated with the corresponding PRI*n* value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

21.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

21.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SELn] bits.

21.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–15 are assigned vectors 0–15, respectively. The peripheral interrupt requests are assigned vectors from 16 to a number as high as needed to cover all peripheral interrupt requests.

21.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*n* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*n*. The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

21.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in Figure 21-1 are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*n*, and if in hardware vector mode, for the interrupt vector provided to the processor.

21.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

21.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

21.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

21.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*n*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*n*, or the PRI value in the associated INTC_CPR*n* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated

INTC_CPR*n* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI*n* in INTC_PSR*n* are zero will not cause a preemption because their PRI*n* will not be higher than PRI in the associated INTC_CPR*n*.

Another function of the comparator is to signal an update of the INTC_IACKR*n* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*n* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

21.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*n*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*n* does not need to be loaded from the associated INTC_CPR*n* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR*n*.

The PRI value in the associated INTC_CPR*n* is pushed onto the LIFO when the associated INTC_IACKR*n* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*n* whenever the associated INTC_EOIR*n* is written. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

Although the INTC supports up to 32 priorities, an ISR executing with PRI in the INTC_CPR*n* equal to 31 will not be preempted. Therefore, the LIFO supports the stacking of 31 priorities. However, the LIFO is only 30 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 31 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

21.6.3 Handshaking with processor

This section describes handshaking with the processor.

21.6.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

21.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to Figure 21-3.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 21-3. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in Software vector mode.

21.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*n* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*n*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*n* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

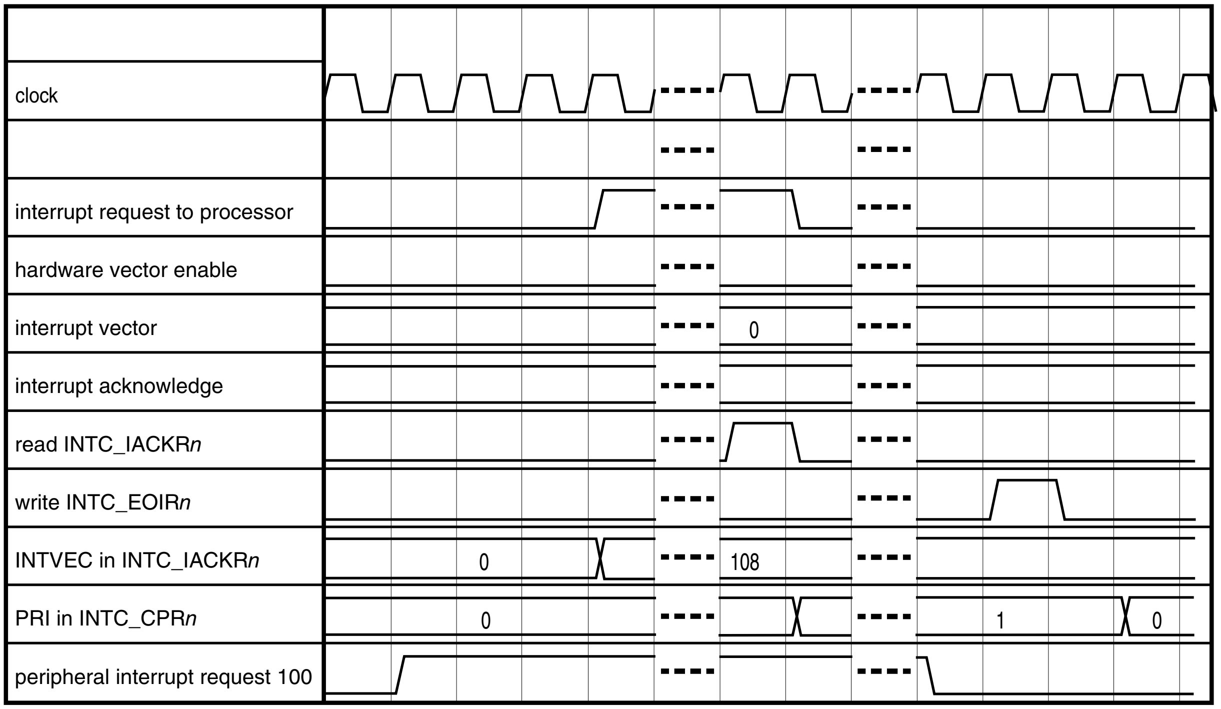

Figure 21-3. Timing diagram of software vector mode handshaking

21.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 21-4. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*n*. The rest of the handshaking is described in Hardware vector mode.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*n*, is the same as in software vector mode. See End of interrupt exception handler.

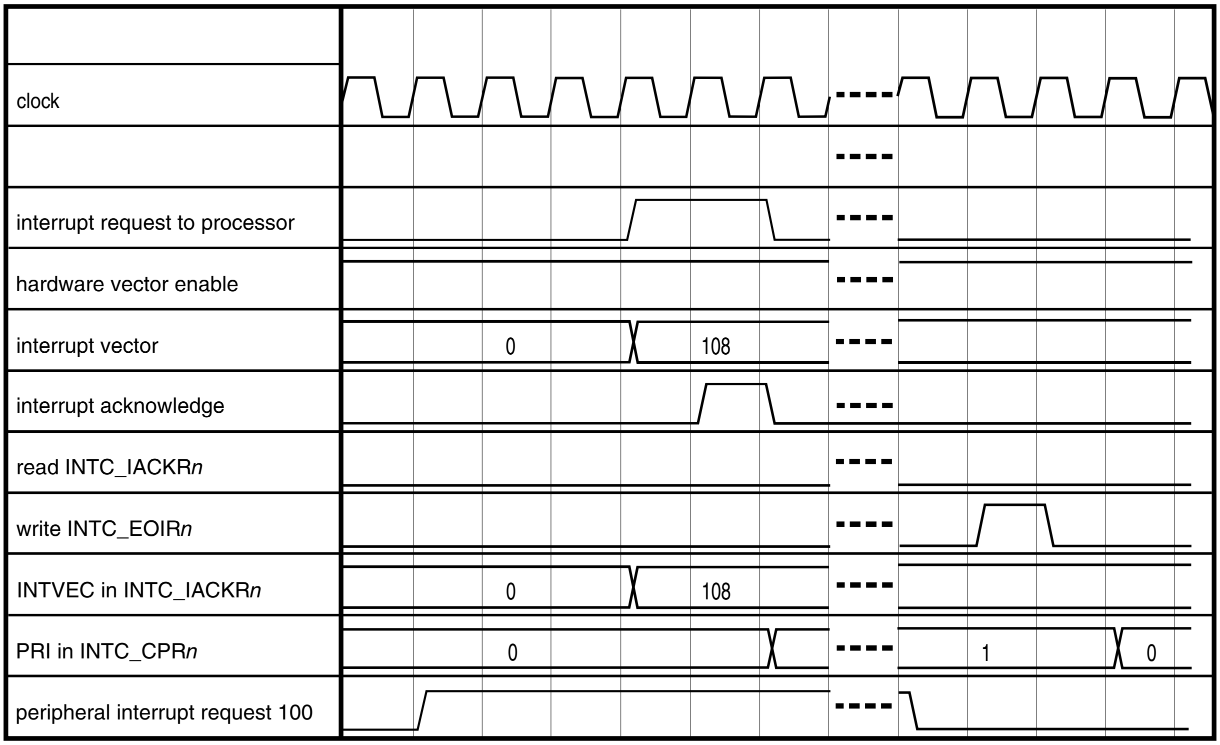

Figure 21-4. Timing diagram for hardware vector mode handshaking

21.6.4 Interrupt Controller Monitor (INTCM)

Isolated in its own hierarchy, the interrupt latency monitor logic is used to monitor or check interrupt latency for reliability, safety, and interrupt software requirements.

21.6.4.1 Operation

The following section lists the operation of the INTCM.

21.6.4.1.1 TIMERn

A clear of TIMERn will clear the corresponding error.

The TIMERn will not run if there is a corresponding error.

If the INTC_MMRn[MM] is enabled and an error is signaled, disable TIMERn.

If the INTC_MMRn[MM] is enabled, for a transition from 0 to 1 of SOURCE input that is being monitored by INTC_HIPRIn registers, clear and enable TIMERn. Once the timer reaches the maximum count, it will stop and not roll over. Software can read the TIMERn value at any time.

If the INTC_MMRn[MM] is enabled and if the TIMERn is enabled, then it should increment each cycle.

If the INTC_MMRn[MM] is enabled and if INTC_LATn is non-zero, an error will be signaled if the timer exceeds INTC_LATn or if the TIMERn reaches the maximum count.

If the INTC_MMRn[MM] is IACK and an interrupt acknowledge asserts for the monitored source, INTC_HIPRIn[IRQ], then the enabled TIMERn should stop. As an extra check, the IRQ is used to ensure that the acknowledged interrupt matches the monitored interrupt INTC_HIPRIn[IRQ].

If the INTC_MMRn[MM] is SW and an interrupt acknowledge occurs where a monitored interrupt is preempted, the enabled TIMERn should stop.

If the INTC_MMRn[MM] is EOI or SW for a monitored interrupt which has an INTC_EOIRn, the enabled TIMERn should stop.

If the INTC_MMRn[MM] is SW and if INTC_EOIRn, and if the previous one is monitored, it will be re-enabled.

21.7 Initialization/application information

This section contains initialization/application information.

21.7.1 Initialization flow

After exiting reset, all of the PRI*n* and PRC_SEL*n* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPRn registers is 31. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt_request_initialization:
    - Configure HVENn in INTC_BCR.
    - Configure VTBAn in INTC_IACKRn.
    - Raise the PRIn fields and set the PRC_SELn fields to the desired processor in INTC_PSRn.
    - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
    - Lower PRI in INTC_CPRn to zero.
    - Enable processor(s) recognition of interrupts.

21.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

21.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

```

21.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*n* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR*n* priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR*n* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPRn priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*n* while the shared resource is being accessed.

An ISR whose PRI*n* in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

21.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 21-1. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3

Table continues on the next page...

Table 21-1. Order of ISR execution example (continued)

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108[1]	ISR208	ISR308	ISR408	interrupt exception handler	
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	0
12	RTOS continues execution.	X						0

[1] ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

21.7.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

21.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*n*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR*n* to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*n* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

21.7.5.2 Ensuring coherency

This section discusses how to ensure coherency.

21.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*n*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*n* can be made by those system services with the code sequence:

```
GetResource:
        wrteei 0                # disable external interrupts to the Processor
        raise PRI                # Write to CPR, cache inhibit, guarded
        mbar                    # flush out writes from store buffer
        wrteei 1                # enable external interrupts to the Processor
        isync                    # re-fetch Processor pipeline

ReleaseResource:
        mbar                    # flush out writes from store buffer
        wrteei 0                # disable external interrupts to the Processor
        lower PRI                # Write to CPR, cache inhibit, guarded
        wrteei 1                # enable external interrupts to the Processor
```

21.7.5.2.1.1 Interrupt request to processor

Referencing Figure 21-1, the interrupt request logic to the processor is shown in the following figure.

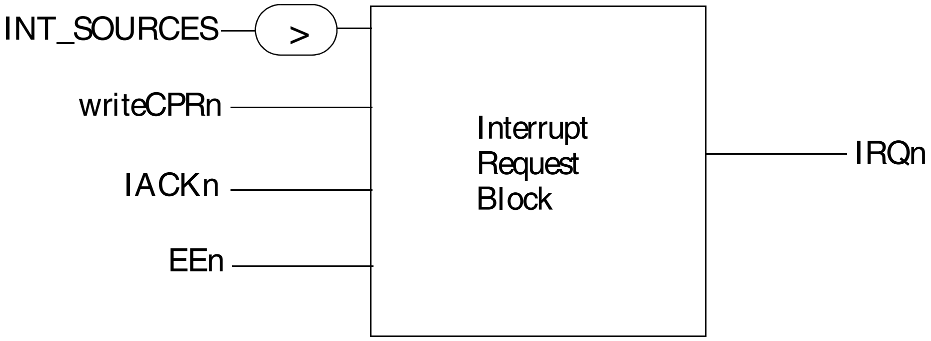

Figure 21-5. Interrupt Request Block Diagram

Assuming that there are no IRQn deasserted (no pending interrupt requests to processor n), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPRn, then interrupt request to the processor (IRQn) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACK) is asserted
- If the EEn bit has been cleared by the wrteei instruction (see the code sequence in Interrupt with blocked priority), IRQn will be re-evaluated when processor n writes to the INTC_CPRn while processor n ignores IRQn

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the INTC_CPRn.

21.7.5.2.2 Raised priority preserved

Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. The following figure shows the timing diagram for this scenario, and the following table explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 21-6. Timing diagram of raised priority preserved

Table 21-2. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	Write to msree bit to disable external interrupts
D	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
E	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
F	Write to msree bit to enable external interrupts

21.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 32 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

21.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

21.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRIn value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*n* with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit in INTC_SSCIR*n*. Writing a '1' to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI*n* value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

21.7.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

21.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in Scheduling a lower priority portion of an ISR) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note

> Lowering the PRI value in INTC_CPR*n* within an ISR to below the ISR's corresponding PRI value in INTC_PSR*n* allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

21.7.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

21.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

21.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

21.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI*n* values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to End of interrupt exception handler for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI*n* value in INTC_PSR*n*.

21.7.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*n*). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPR*n*, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
      wrteei 0                # disable processor recognition of external interrupts
      oldCPRn = INTC_CPRn;    # save INTC_CPRn
      (branch to the pop_lifo)

pop_lifo:
      store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI, etc...
      examine INTC_CPRn[PRI], and store onto stack
      if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
      branch to push_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
      load stacked PRI value and store to INTC_CPRn
      load INTC_IACKn         # IACK; push INTC_CPRn into LIFO
      if stacked PRI values are not depleted, branch to push_lifo

      INTC_CPRn    = oldCPRn; # restore original INTC_CPRn and re-evaluate pending external
interrupts
      wrteei 1                # enable processor recognition of interrupts
```

NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

21.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.

Chapter 22
Enhanced Direct Memory Access (eDMA)

22.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

22.1.1 eDMA system block diagram

Figure 22-1 illustrates the components of the eDMA system, including the eDMA module ("engine").

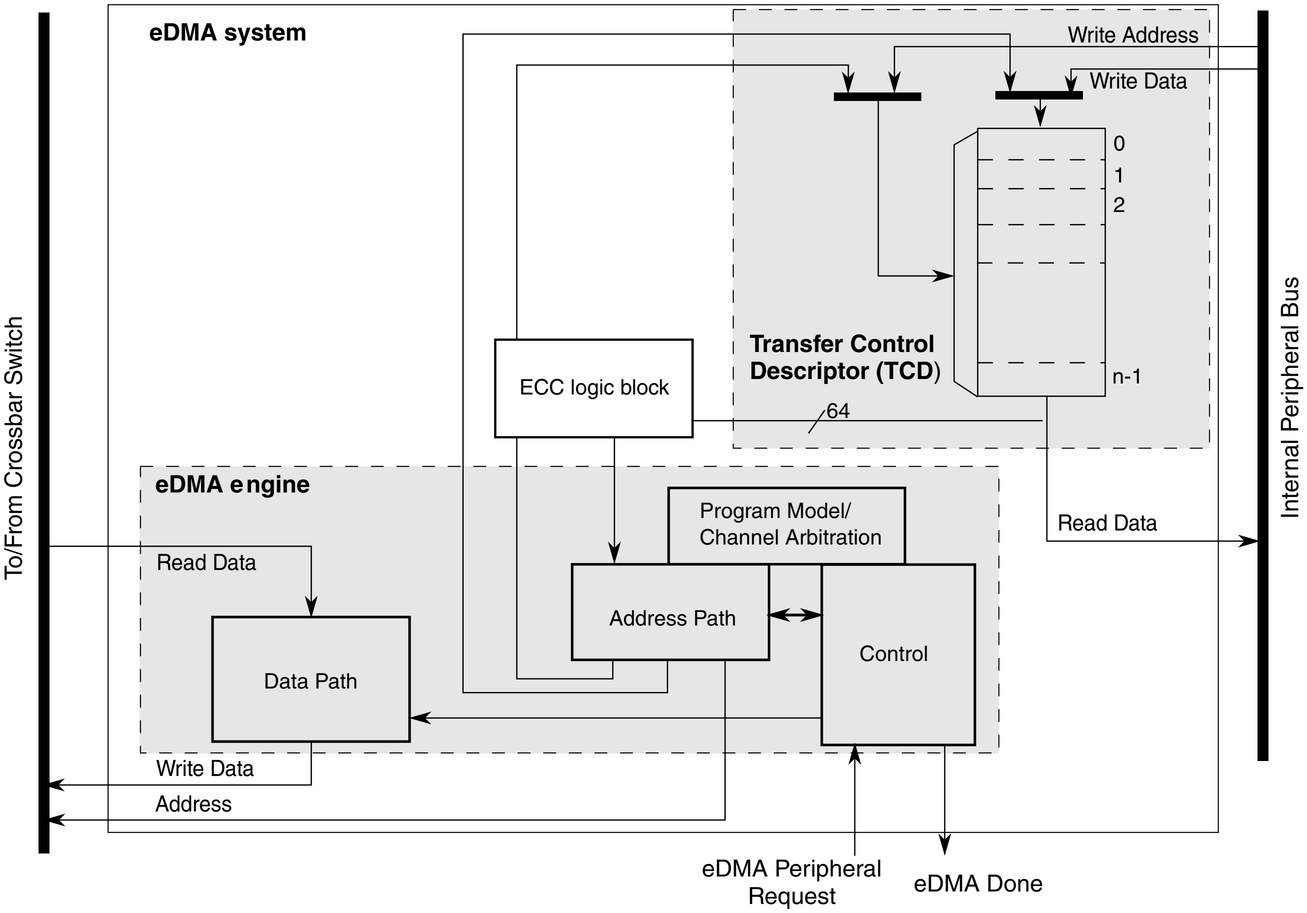

Figure 22-1. eDMA system block diagram

22.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 22-1. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes

Table continues on the next page...

Table 22-1. eDMA engine submodules (continued)

Submodule	Function
	the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 22-2. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

22.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
    - Programmable source and destination addresses and transfer size
    - Support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
    - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
    - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
    - 32-byte TCD stored in local memory for each channel
    - An inner data transfer loop defined by a minor byte transfer count
    - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
    - Explicit software initiation
    - Initiation via a channel-to-channel linking mechanism for continuous transfers
    - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
    - One interrupt per channel, which can be asserted at completion of major iteration count
    - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures
- Error detection and error correction

In the discussion of this module, *n* is used to reference the channel number.

22.2 Modes of operation

The eDMA operates in the following modes:

Table 22-3. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

22.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

22.3.1 TCD memory

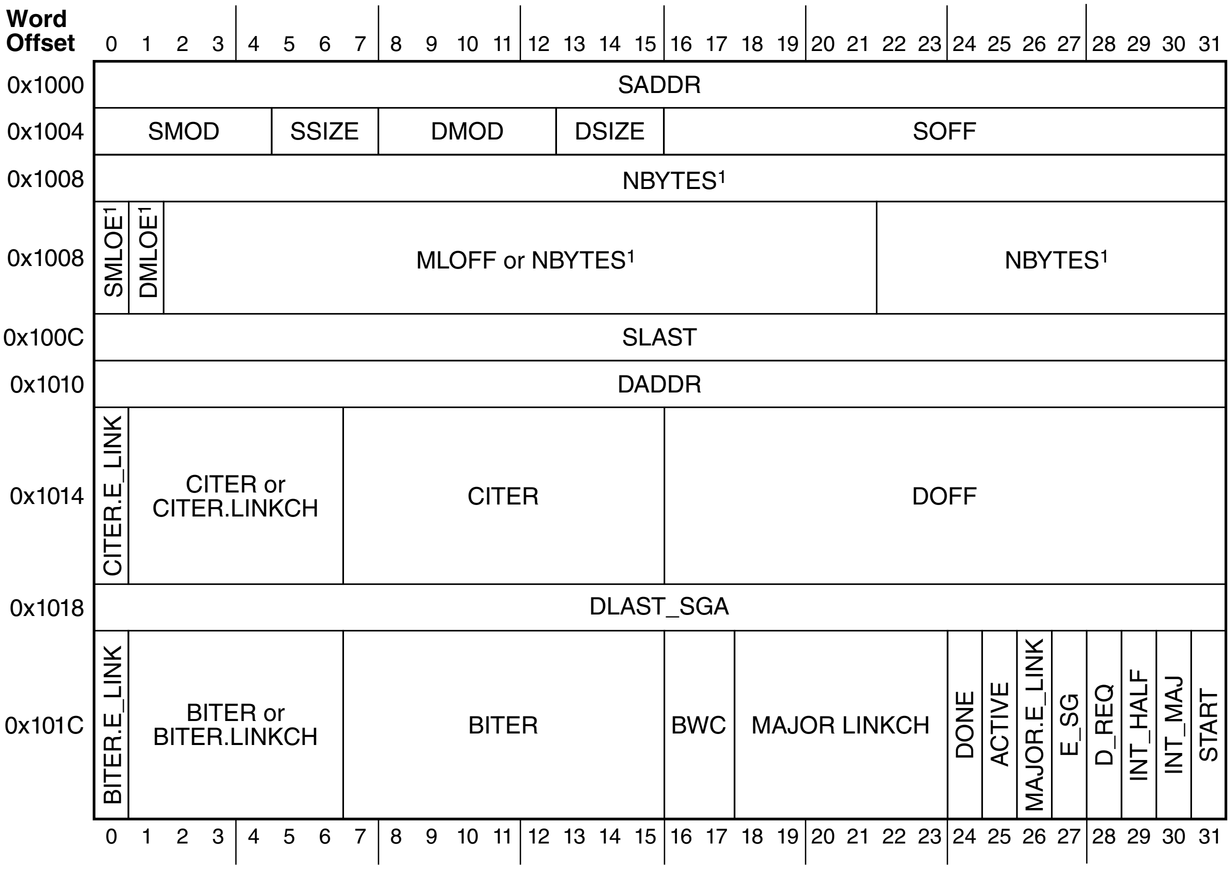
Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

22.3.2 TCD initialization

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

22.3.3 TCD structure

DMA Basics: TCD Structure
- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD



[1] The fields implemented in Word 2 depend on whether EDMA_CR[EMLM] bit is set to 0 or 1.

22.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

22.3.1 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

> For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

DMA_CR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CX	Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
24 EMLM	Enable Minor Loop Mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
25 CLM	Continuous Link Mode **NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA Operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
29 ERCA	Enable Round Robin Channel Arbitration 0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
30 EDBG	Enable Debug 0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
31 Reserved	This field is reserved. Reserved

22.3.2 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle

- A bit in the ES shows an uncorrectable error occurred while the device has ECC protection on the TCD SRAM
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See the Error Reporting and Handling section for more details.

DMA_ES field descriptions

Field	Description
0 VLD	Logical OR of all ERR status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
1–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 UCE	Uncorrectable ECC error during channel execution. The UCE bit is set when an uncorrectable ECC error occurs on an access generated by the DMA only. If a CPU access to the TCD causes an uncorrectable ECC error, that access will receive a bus error response. **NOTE:** When the eDMA sees a RAM error on an IPS access (when the user is accessing a TCD), the error is reported as a bus abort. When the dma_engine (the execution engine is accessing a TCD) receives a RAM error, it is recorded in the Error Status register, DMA_ES[UCE], along with the channel number. 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer Canceled 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
16 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
17 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
24 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
25 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
26 DAE	Destination Address Error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
27 DOE	Destination Offset Error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
28 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or • TCDn_CITER[CITER] is equal to zero, or • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
29 SGE	Scatter/Gather Configuration Error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
30 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
31 DBE	Destination Bus Error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

22.3.3 Enable Request Register (DMA_ERQ)

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

28 ERQ3	Enable DMA Request 3 0 The DMA request signal for the corresponding channel is disabled 1 The DMA request signal for the corresponding channel is enabled
29 ERQ2	Enable DMA Request 2 0 The DMA request signal for the corresponding channel is disabled 1 The DMA request signal for the corresponding channel is enabled
30 ERQ1	Enable DMA Request 1 0 The DMA request signal for the corresponding channel is disabled 1 The DMA request signal for the corresponding channel is enabled
31 ERQ0	Enable DMA Request 0 0 The DMA request signal for the corresponding channel is disabled 1 The DMA request signal for the corresponding channel is enabled

22.3.4 Enable Error Interrupt Register (DMA_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel’s error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

Address: 0h base + 14h offset = 14h

22.3.5 Set Enable Request Register (DMA_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	SAER	0	SERQ				
Reset	0	0	0	0	0	0	0	0

DMA_SERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAER	Set All Enable Requests 0 Set only the ERQ bit specified in the SERQ field 1 Set all bits in ERQ
2 Reserved	This field is reserved.
3–7 SERQ	Set Enable Request Sets the corresponding bit in ERQ.

22.3.6 Clear Enable Request Register (DMA_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 19h offset = 19h

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAER	0	CERQ				
Reset	0	0	0	0	0	0	0	0

DMA_CERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAER	Clear All Enable Requests 0 Clear only the ERQ bit specified in the CERQ field 1 Clear all bits in ERQ
2 Reserved	This field is reserved.
3–7 CERQ	Clear Enable Request Clears the corresponding bit in ERQ.

22.3.7 Set Enable Error Interrupt Register (DMA_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	SAEE	0	SEEI				
Reset	0	0	0	0	0	0	0	0

DMA_SEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAEE	Sets All Enable Error Interrupts 0 Set only the EEI bit specified in the SEEI field. 1 Sets all bits in EEI
2 Reserved	This field is reserved.
3–7 SEEI	Set Enable Error Interrupt Sets the corresponding bit in EEI

22.3.8 Clear Enable Error Interrupt Register (DMA_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Bh offset = 1Bh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAEE	0	CEEI				
Reset	0	0	0	0	0	0	0	0

DMA_CEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEE	Clear All Enable Error Interrupts 0 Clear only the EEI bit specified in the CEEI field 1 Clear all bits in EEI
2 Reserved	This field is reserved.
3–7 CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI

22.3.9 Clear Interrupt Request Register (DMA_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAIR	0	CINT				
Reset	0	0	0	0	0	0	0	0

DMA_CINT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAIR	Clear All Interrupt Requests 0 Clear only the INT bit specified in the CINT field 1 Clear all bits in INT
2 Reserved	This field is reserved.
3–7 CINT	Clear Interrupt Request Clears the corresponding bit in INT

22.3.10 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Dh offset = 1Dh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAEI	0	CERR				
Reset	0	0	0	0	0	0	0	0

DMA_CERR field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEI	Clear All Error Indicators 0 Clear only the ERR bit specified in the CERR field 1 Clear all bits in ERR
2 Reserved	This field is reserved.
3–7 CERR	Clear Error Indicator Clears the corresponding bit in ERR

22.3.11 Set START Bit Register (DMA_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Eh offset = 1Eh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	SAST	0	SSRT				
Reset	0	0	0	0	0	0	0	0

DMA_SSRT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAST	Set All START Bits (activates all channels) 0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
2 Reserved	This field is reserved.
3–7 SSRT	Set START Bit Sets the corresponding bit in TCDn_CSR[START]

22.3.12 Clear DONE Status Bit Register (DMA_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Fh offset = 1Fh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CADN	0	CDNE				
Reset	0	0	0	0	0	0	0	0

DMA_CDNE field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
2 Reserved	This field is reserved.
3–7 CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

22.3.13 Interrupt Request Register (DMA_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

Address: 0h base + 24h offset = 24h

22.3.14 Error Register (DMA_ERR)

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software’s responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

22.3.15 Hardware Request Status Register (DMA_HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Address: 0h base + 34h offset = 34h

22.3.16 Channel n Priority Register (DMA_DCHPRI*n*)

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: 0h base + 100h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	ECP	DPA	GRPPRI		CHPRI			
Write			▨	▨				
Reset	0	0	*	*	*	*	*	*

* Notes:
- CHPRI field: See bit field description.
- GRPPRI field: See bit field description.

DMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable Channel Preemption. 0 Channel n cannot be suspended by a higher priority channel’s service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.

Table continues on the next page...

DMA_DCHPRI*n* field descriptions (continued)

Field	Description
1 DPA	Disable Preempt Ability. 0 Channel n can suspend a lower priority channel. 1 Channel n cannot suspend any channel, regardless of channel priority.
2–3 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored. **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4–7 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.

22.3.17 Channel n Master ID Register (DMA_DCHMID*n*)

The DMA master ID replication registers allow the DMA to use the same protection level and system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master, for example, a core, programs a TCD, its master ID and protection level are captured when the TCDn.CSR control attributes are written. Although the scatter/gather operation can change the contents of TCDn_CSR, that operation does not affect the DCHMID *n* registers.

Address: 0h base + 140h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	EMI	PAL	0		MID			
Write								
Reset	0	0	0	0	0	0	0	0

DMA_DCHMID*n* field descriptions

Field	Description
0 EMI	Enable Master ID replication **NOTE:** If Master ID replication is disabled, the privileged protection level (supervisor mode) for DMA transfers is used.

Table continues on the next page...

DMA_DCHMID*n* field descriptions (continued)

Field	Description
	0 Master ID replication is disabled 1 Master ID replication is enabled
1 PAL	Privileged Access Level **NOTE:** The protection level captured in this register reflects the level used when writing the channel's control attributes; lower byte of TCDn.CSR. 0 User protection level for DMA transfers 1 Privileged protection level for DMA transfers
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MID	Master ID DMA's master ID when channel n is active and master ID replication is enabled. **NOTE:** The master ID captured in this register reflects the ID used when writing the channel's control attributes; lower byte of TCDn.CSR.

22.3.18 TCD Source Address (DMA_TCD*n*_SADDR)

Address: 0h base + 1000h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SADDR field descriptions

Field	Description
0–31 SADDR	Source Address Memory address pointing to the source data.

22.3.19 TCD Transfer Attributes (DMA_TCD*n*_ATTR)

Address: 0h base + 1004h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMOD					SSIZE			DMOD					DSIZE		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_ATTR field descriptions

Field	Description
0–4 SMOD	Source Address Modulo 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5–7 SSIZE	Source data transfer size **NOTE:** Using a Reserved value causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte burst (4 beats of 64 bits) 110 Reserved 111 Reserved
8–12 DMOD	Destination Address Modulo See the SMOD definition
13–15 DSIZE	Destination data transfer size See the SSIZE definition

22.3.20 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF)

Address: 0h base + 1006h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SOFF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SOFF field descriptions

Field	Description
0–15 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

22.3.21 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCD*n*_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NBYTES																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **NOTE:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

22.3.22 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	SMLOE	DMLOE	NBYTES

R W	NBYTES															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

22.3.23 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DMA_TCD*n*_SLAST field descriptions

Field	Description
0–31 SLAST	Last Source Address Adjustment Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure. This register uses two's complement notation; the overflow bit is discarded.

22.3.25 TCD Destination Address (DMA_TCD*n*_DADDR)

Address: 0h base + 1010h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA_TCD*n*_DADDR field descriptions

Field	Description
0–31 DADDR	Destination Address Memory address pointing to the destination data.

22.3.26 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES)

If TCDn_CITER[ELINK] is set, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	ELINK		LINKCH					CITER
Write		0						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	CITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1 Reserved	This field is reserved.
2–6 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7–15 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

22.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO)

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7

DMA_TCD*n*_DLASTSGA field descriptions

Field	Description
0–31 DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

22.3.30 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7

Read Write	BITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_BITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1 Reserved	This field is reserved.
2–6 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
7–15 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

22.3.31 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_BITER_ELINKNO)

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	BITER

Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CSR field descriptions

Field	Description
0–1 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls. 01 Reserved 10 eDMA engine stalls for 4 cycles after each R/W. 11 eDMA engine stalls for 8 cycles after each R/W.
2 Reserved	This field is reserved.
3–7 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
8 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. **NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits.
9 ACTIVE	Channel Active This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.

Table continues on the next page...

DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
11 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0 The channel's ERQ bit is not affected. 1 The channel's ERQ bit is cleared when the major loop is complete.
13 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
14 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
15 START	Channel Start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution.

Table continues on the next page...

DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
	0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

22.4 Functional description

The operation of the eDMA is described in the following subsections.

22.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

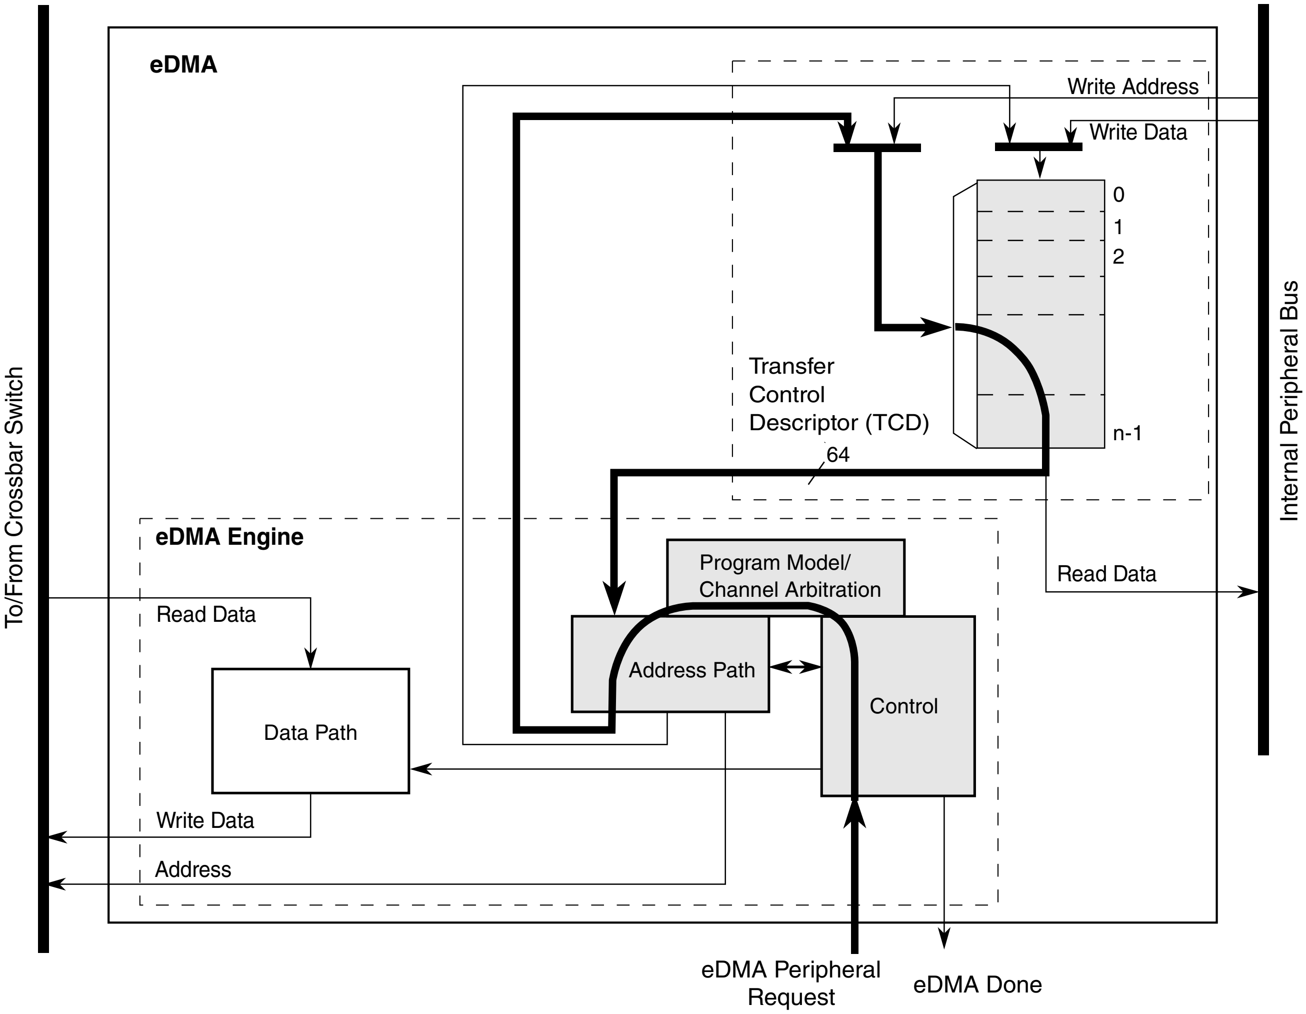

Figure 22-2. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

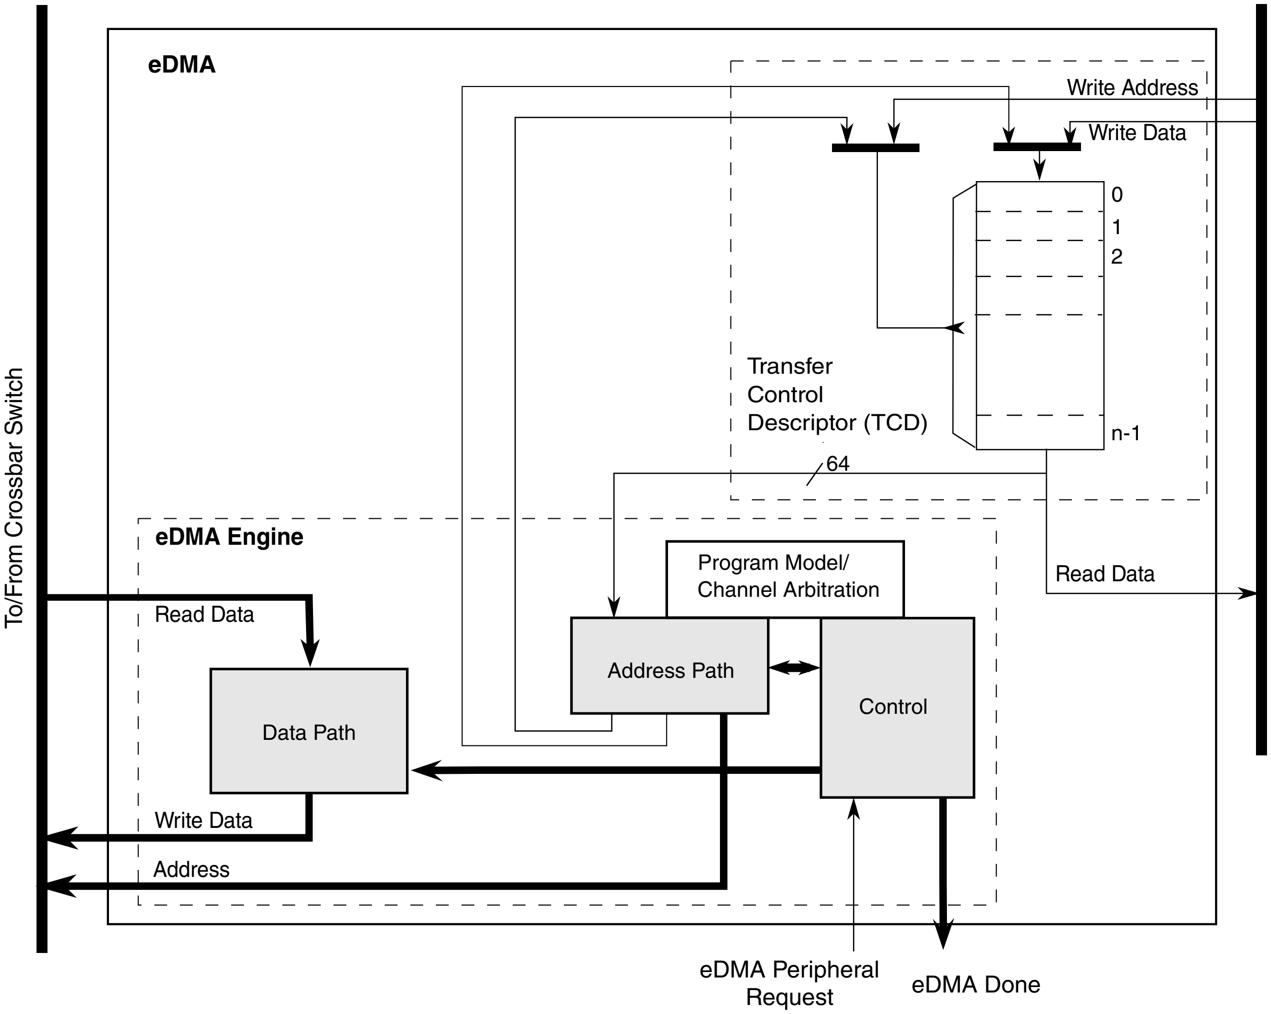

Figure 22-3. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

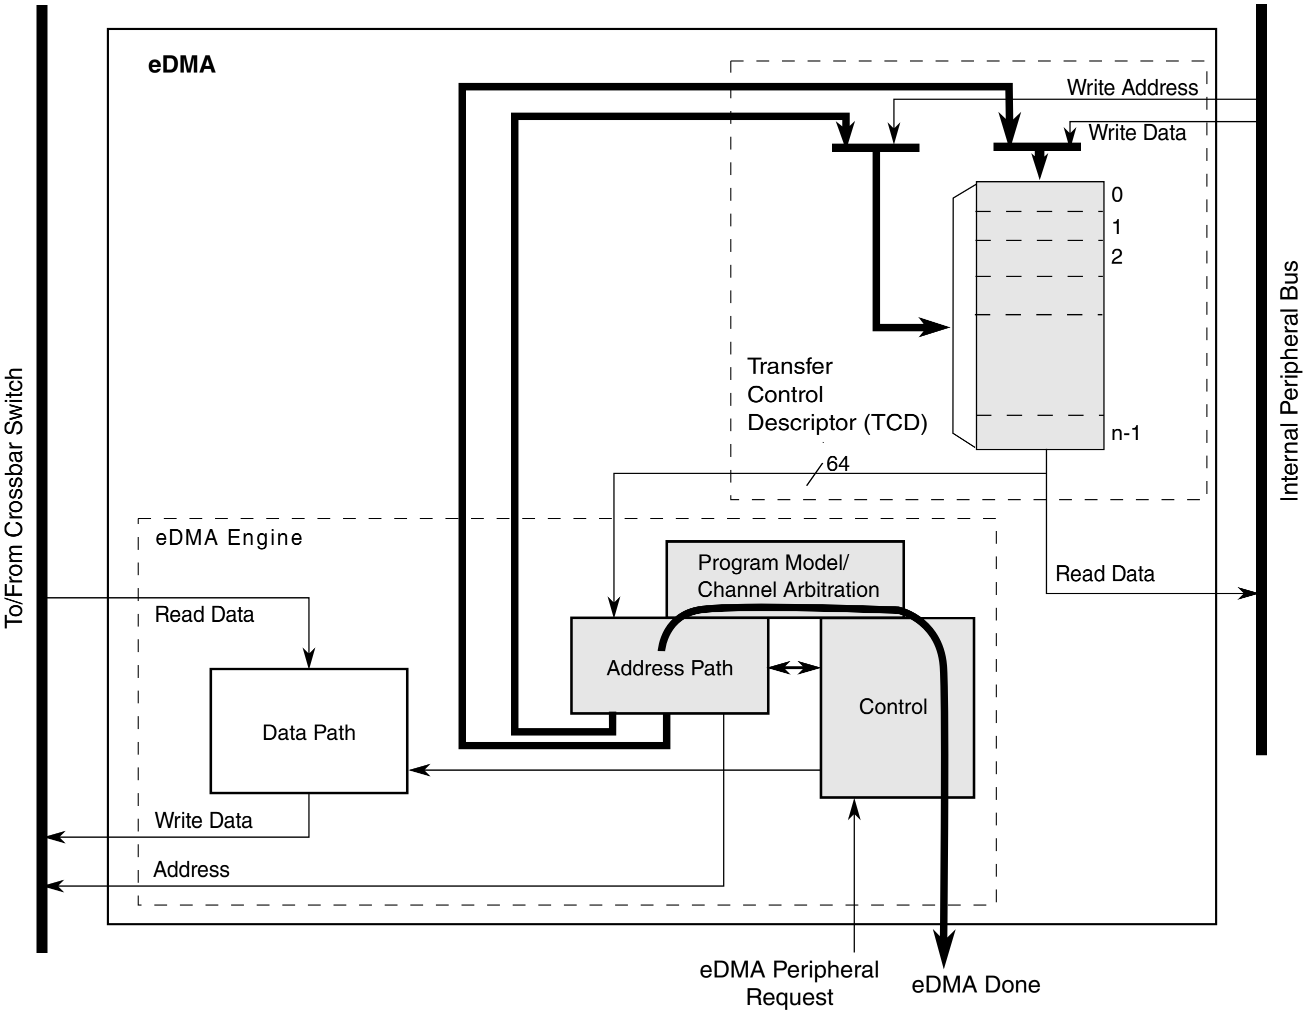

Figure 22-4. eDMA operation, part 3

22.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.

- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration in undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

> The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

22.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

22.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

22.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

NOTE

All architectures will not meet the assumptions listed above. See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

Table 22-4. eDMA peak transfer rates (Mbytes/sec)

System Speed, Width	Internal SRAM-to- Internal SRAM	32 bit internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32 bit internal peripheral bus
66.7 MHz, 64 bit	266.7	66.6	53.3
83.3 MHz, 64 bit	333.3	83.3	66.7
100.0 MHz, 64 bit	400.0	100.0	80.0
133.3 MHz, 64 bit	533.3	133.3	106.7
150.0 MHz, 64 bit	600.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

22.4.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 22-5. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD*n*_CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* word 7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* word 7 is read and checked for channel linking or scatter/gather requests.
14	15	The appropriate fields in the first part of the TCD*n* are written back into the local memory.
15	16	The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles (4 + (4+5)/2 + 3). This is the time from Cycle 4 to Cycle x +5. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

Table 22-6. eDMA peak request rate (MReq/sec)

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]

where:

Table 22-7. Peak request formula operands

Operand	Description
PEAKreq	Peak request rate
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase
exit	Channel shutdown (3 cycles)

22.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer, PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 3) + 3] cycles = 11.5 Mreq/sec

For an internal peripheral bus to SRAM transfer,

PEAKreq = 150 MHz / [4 + (1 + 2) + (1 + 1) + 3] cycles = 12.5 Mreq/sec

Assuming an even distribution of the two transfer types, the average peak request rate would be:

PEAKreq = (11.5 Mreq/sec + 12.5 Mreq/sec) / 2 = 12.0 Mreq/sec

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD*n*_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

22.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

22.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.

3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQH and ERQL registers.
6. Request channel service via either:
   - Software: setting the TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 22-8. TCD Control and Status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

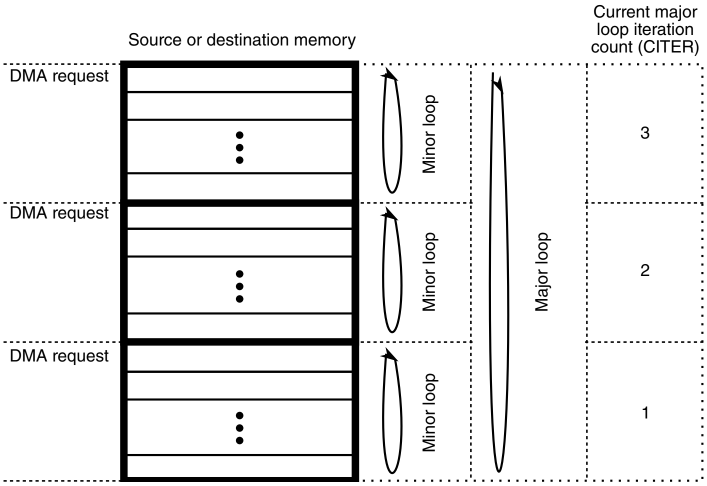

Figure 22-5. Example of multiple loop iterations

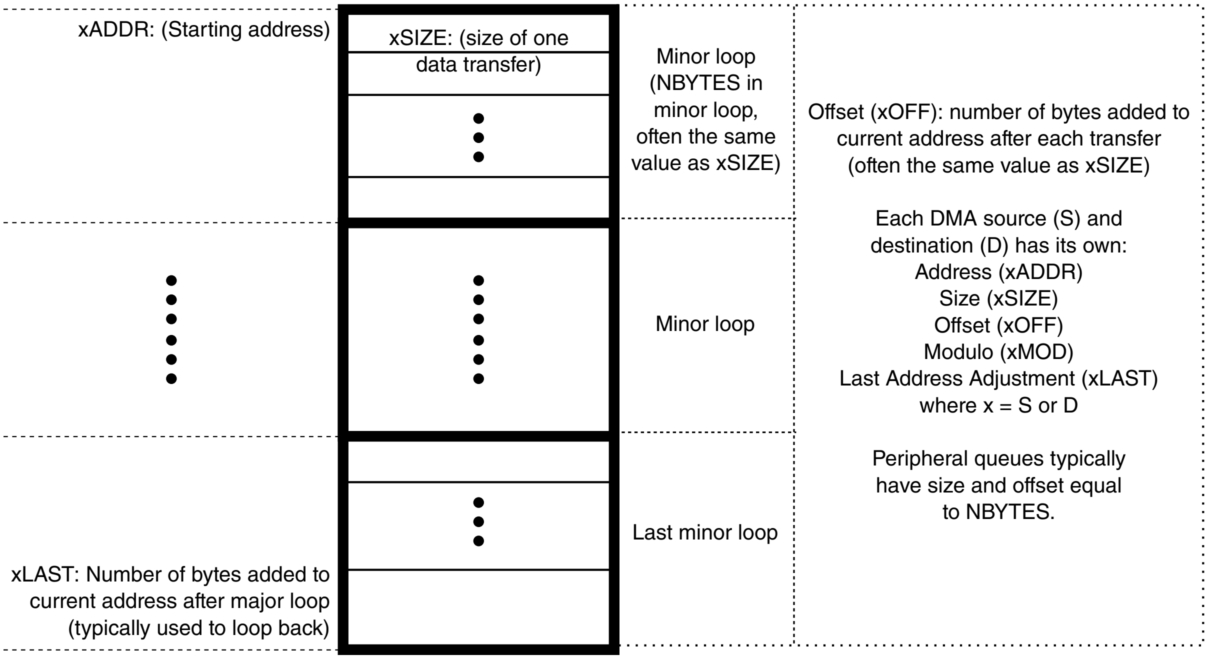
The following figure lists the memory array terms and how the TCD settings interrelate.



xADDR: (Starting address)
xSIZE: (size of one data transfer)
Minor loop (NBYTES in minor loop, often the same value as xSIZE)
Offset (xOFF): number of bytes added to current address after each transfer (often the same value as xSIZE)
Each DMA source (S) and destination (D) has its own:
Address (xADDR)
Size (xSIZE)
Offset (xOFF)
Modulo (xMOD)
Last Address Adjustment (xLAST)
where x = S or D
Peripheral queues typically have size and offset equal to NBYTES.
Minor loop
Last minor loop
xLAST: Number of bytes added to current address after major loop (typically used to loop back)

Figure 22-6. Memory array terms

22.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

22.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

22.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

22.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

22.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

22.5.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

22.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32-bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

22.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 22-9. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

22.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

22.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

22.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and

DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

22.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

22.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit

2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

> The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 22-10. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

22.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

22.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

22.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution (see the diagram in TCD structure). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e_link bit.
2. Read back the TCD.major.e_link bit.
3. Test the TCD.major.e_link request status:
    - If TCD.major.e_link = 1, the dynamic link attempt was successful.
    - If TCD.major.e_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

22.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources.When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

22.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD indentification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

3. Write the TCD.dlast_sga field with the scatter/gather address.
4. Write 1b to the TCD.e_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e_sg request status and TCD.major.linkch value:

   If e_sg = 1b, the dynamic link attempt was successful.

   If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

22.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD indentification (ID).

1. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

2. Write theTCD.dlast_sga field with the scatter/gather address.
3. Write 1b to the TCD.e_sg bit.
4. Read back the TCD.e_sg bit.
5. Test the TCD.e_sg request status:

   If e_sg = 1b, the dynamic link attempt was successful.

   If e_sg = 0b, read the 32 bit TCD dlast_sga field.

   If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

Chapter 23
Direct Memory Access Multiplexer (DMAMUX)

23.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

23.1.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

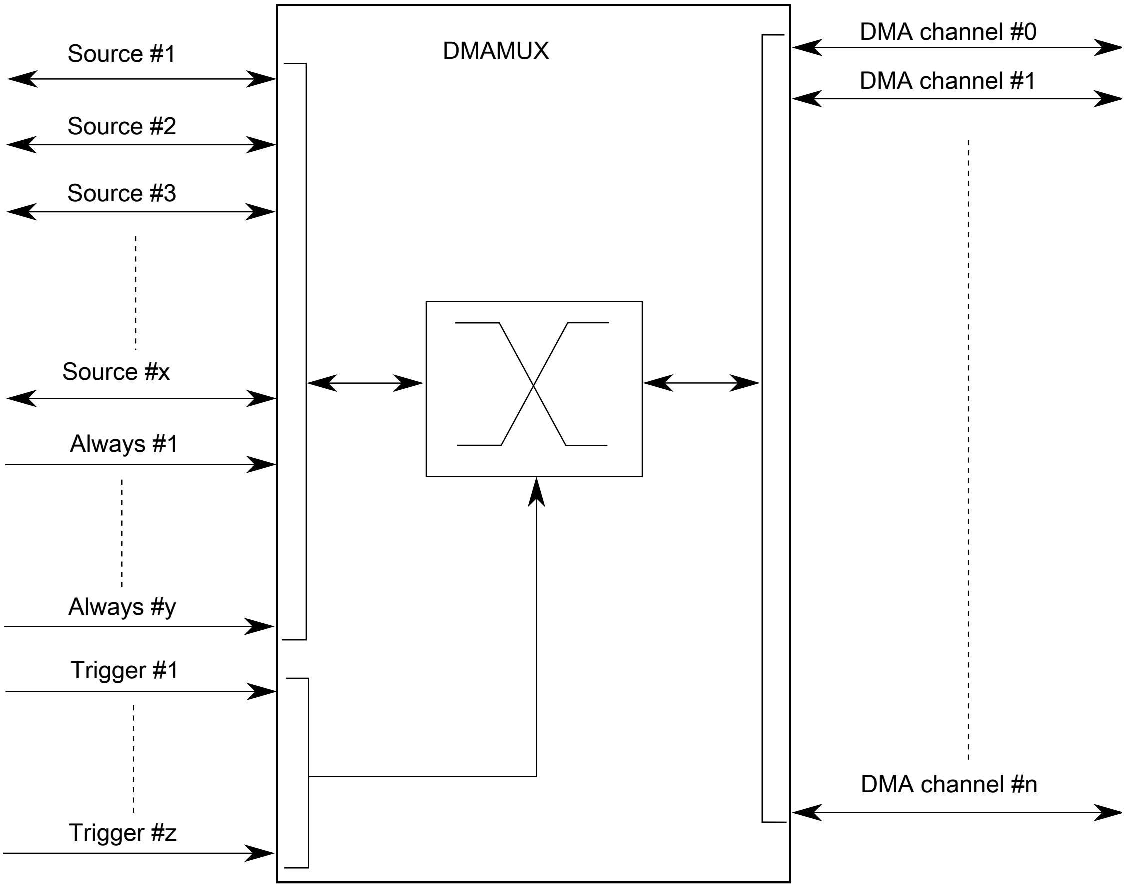


Figure 23-1. DMAMUX block diagram

23.1.2 Features

The DMAMUX module provides these features:

- Up to 27 peripheral slots and up to six always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
    - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

23.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

23.2 External signal description

The DMAMUX has no external pins.

23.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel Configuration register (DMAMUX_CHCFG0)	8	R/W	00h	23.3.1/742
1	Channel Configuration register (DMAMUX_CHCFG1)	8	R/W	00h	23.3.1/742
2	Channel Configuration register (DMAMUX_CHCFG2)	8	R/W	00h	23.3.1/742
3	Channel Configuration register (DMAMUX_CHCFG3)	8	R/W	00h	23.3.1/742
4	Channel Configuration register (DMAMUX_CHCFG4)	8	R/W	00h	23.3.1/742
5	Channel Configuration register (DMAMUX_CHCFG5)	8	R/W	00h	23.3.1/742
6	Channel Configuration register (DMAMUX_CHCFG6)	8	R/W	00h	23.3.1/742
7	Channel Configuration register (DMAMUX_CHCFG7)	8	R/W	00h	23.3.1/742
8	Channel Configuration register (DMAMUX_CHCFG8)	8	R/W	00h	23.3.1/742

Table continues on the next page...

DMAMUX memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
9	Channel Configuration register (DMAMUX_CHCFG9)	8	R/W	00h	23.3.1/742
A	Channel Configuration register (DMAMUX_CHCFG10)	8	R/W	00h	23.3.1/742
B	Channel Configuration register (DMAMUX_CHCFG11)	8	R/W	00h	23.3.1/742
C	Channel Configuration register (DMAMUX_CHCFG12)	8	R/W	00h	23.3.1/742
D	Channel Configuration register (DMAMUX_CHCFG13)	8	R/W	00h	23.3.1/742
E	Channel Configuration register (DMAMUX_CHCFG14)	8	R/W	00h	23.3.1/742
F	Channel Configuration register (DMAMUX_CHCFG15)	8	R/W	00h	23.3.1/742

23.3.1 Channel Configuration register (DMAMUX_CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

> Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).
>
> Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read Write	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

DMAMUX_CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel.

Table continues on the next page...

DMAMUX_CHCFG*n* field descriptions (continued)

Field	Description
	0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
2–7 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

23.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

23.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

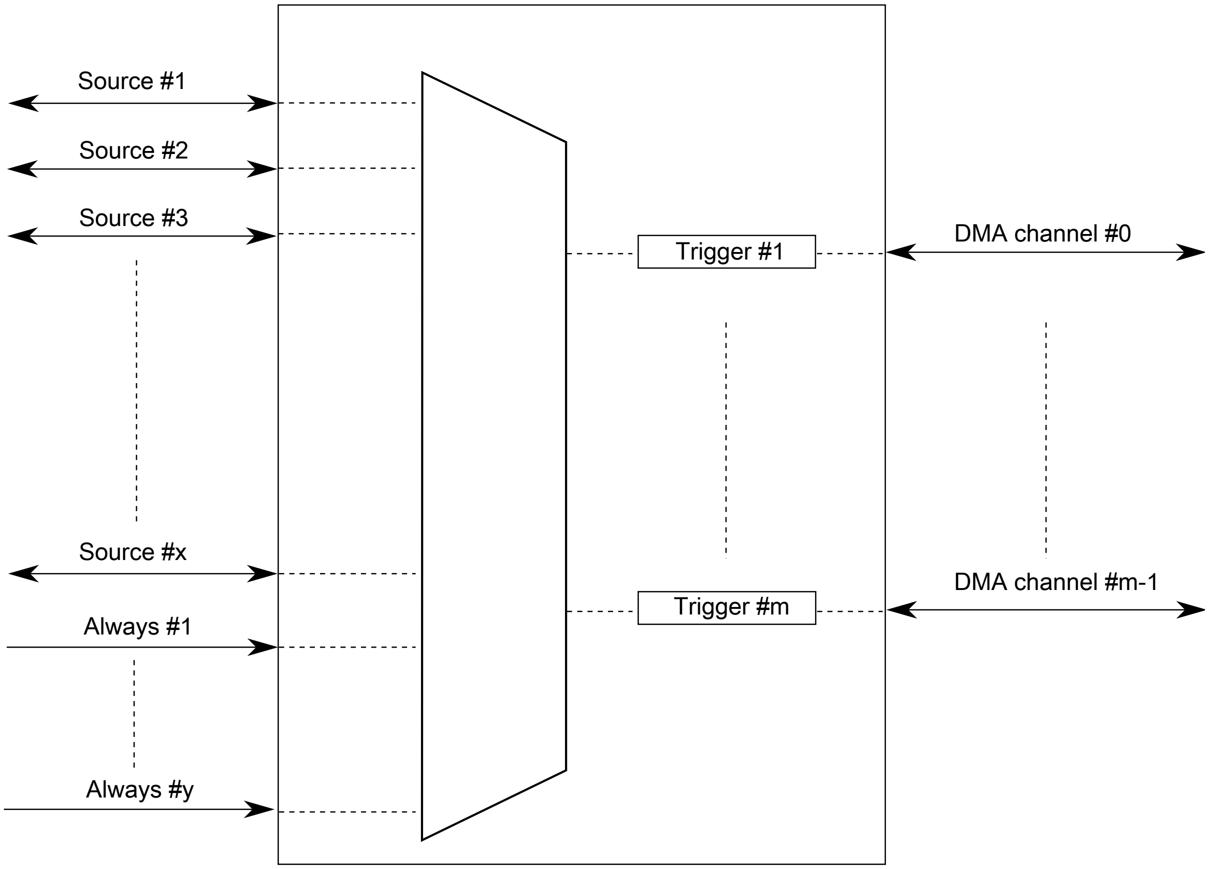

Figure 23-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

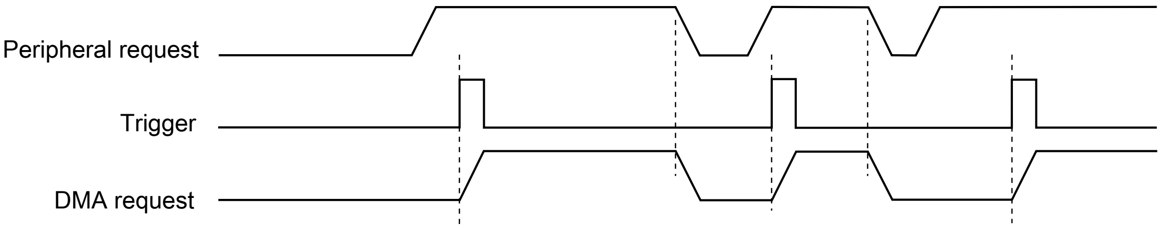

Figure 23-3. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

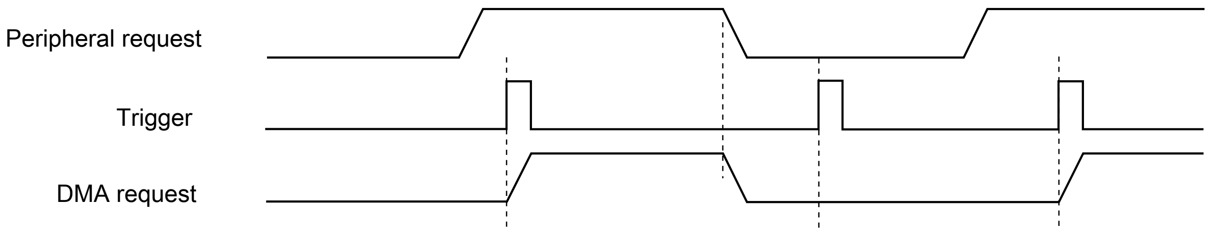

Figure 23-4. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 μs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

23.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

23.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are six additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

23.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

23.5.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

23.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

> The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

Chapter 24
Error Injection Module (EIM)

24.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Error Injection module is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of the peripheral memories. See the chip-specific EIM information to determine which peripheral memories are supported by this method.

24.1.1 Overview

The Error Injection Module (EIM) provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

NOTE

> The following diagram shows an example EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

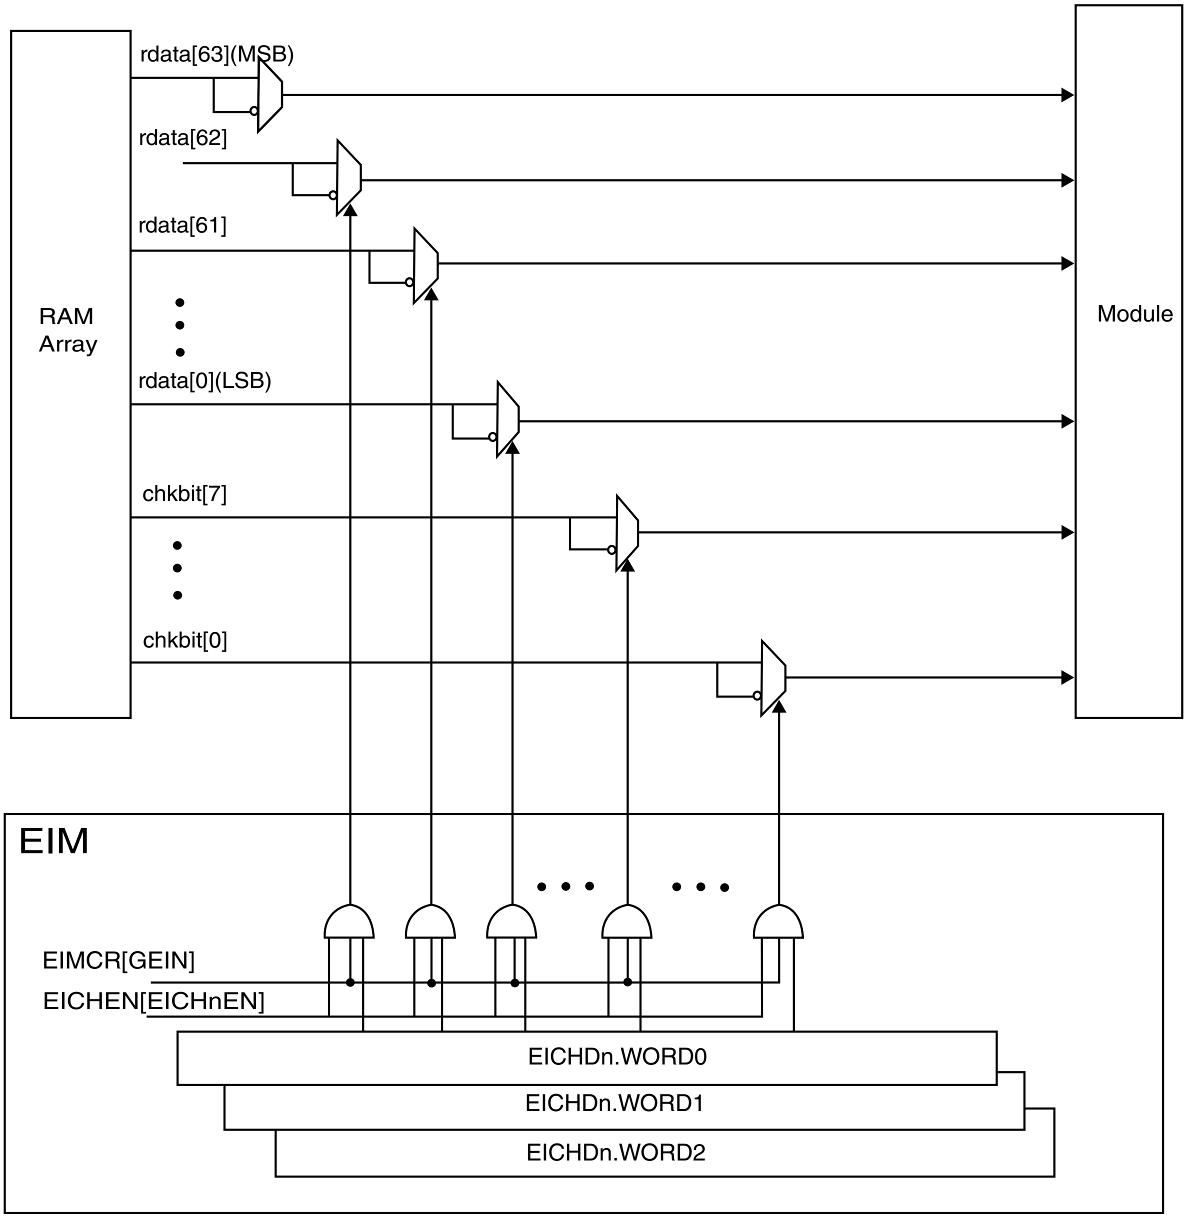

Figure 24-1. EIM functional block diagram (64-bit read data bus and 8-bit checkbit bus)

24.1.2 Features

The EIM includes these features:

- Supports 1 error injection channel
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

24.2 Memory map and register definition

The EIM provides an IPS programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation will result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model.
    - Each descriptor consists of Error Injection Channel Descriptor Word0-1 (EICHD*n*_WORD0-1) and, depending on the implementation, Word2 (EICHD*n*_WORD2).
    - When Word2 is unused, the corresponding word in the 16-byte structure is unused.
    - The fourth word in the 16-byte structure is always unused.

EIM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Error Injection Module Configuration Register (EIM_EIMCR)	32	R/W	0000_0000h	24.2.1/754
4	Error Injection Channel Enable register (EIM_EICHEN)	32	R/W	0000_0000h	24.2.2/755
100	Error Injection Channel Descriptor, Word0 (EIM_EICHD0_WORD0)	32	R/W	0000_0000h	24.2.3/756
104	Error Injection Channel Descriptor, Word1 (EIM_EICHD0_WORD1)	32	R/W	0000_0000h	24.2.4/757
108	Error Injection Channel Descriptor, Word2 (EIM_EICHD0_WORD2)	32	R/W	0000_0000h	24.2.5/757

24.2.1 Error Injection Module Configuration Register (EIM_EIMCR)

The EIM Configuration Register is used to globally enable/disable the error injection function.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															GEIEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EIMCR field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0 Disabled 1 Enabled

24.2.2 Error Injection Channel Enable register (EIM_EICHEN)

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

> To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EICH0EN	0														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHEN field descriptions

Field	Description
0 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. This field is cleared by power-on reset and unaffected by other types of system reset. 0 Error injection is disabled on Error Injection Channel 0 1 Error injection is enabled on Error Injection Channel 0
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

24.2.3 Error Injection Channel Descriptor, Word0 (EIM_EICHD*n*_WORD0)

The first word of the Error Injection Channel Descriptor defines a left-justified mask field (CHKBIT_MASK) whose width is up to 8 bits. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Address: 0h base + 100h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHD*n*_WORD0 field descriptions

Field	Description
0–7 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. The width of the field for the channel is defined in the chip-specific EIM information. 0 The corresponding bit of the checkbit bus remains unmodified. 1 The corresponding bit of the checkbit bus is inverted.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

24.2.4 Error Injection Channel Descriptor, Word1 (EIM_EICHD*n*_WORD1)

The second word of the Error Injection Channel Descriptor defines the bits in the mask corresponding to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Address: 0h base + 104h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHD*n*_WORD1 field descriptions

Field	Description
0–31 B0_3DATA_ MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 0-3 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 0-3 on the read data bus remains unmodified 1 The corresponding bit of bytes 0-3 on the read data bus is inverted.

24.2.5 Error Injection Channel Descriptor, Word2 (EIM_EICHD*n*_WORD2)

The third word of the Error Injection Channel Descriptor, when present, defines the bits in the mask corresponding to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Address: 0h base + 108h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	B4_7DATA_MASK																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHD*n*_WORD2 field descriptions

Field	Description
0–31 B4_7DATA_ MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 4-7 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1 The corresponding bit of bytes 4-7 on the read data bus is inverted.

24.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel, execute both of the following:

- Assert the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.
- Assert EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 1 error injection channel. Each channel:

- is assigned to a single memory array interface.
- intercepts the assigned memory read data bus and checkbit bus and injects errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 24-1 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Chapter 25
Dual PLL Digital Interface (PLLDIG)

25.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Dual PLL system composed of PLL0 and PLL1 analog blocks and the digital interface (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

A key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1.

25.2 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

25.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.

- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
    - The loss of lock indication is sent to the FCCU via the system glue logic.

25.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. PLLDIG operates in normal mode with a reference clock and PLL enabled.

NOTE

Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<*mode*>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLLs. When using a crystal for the reference clock, reset should remain asserted until the oscillator has stabilized.

25.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In normal mode, PLL0 receives an input clock from the reference which can be prescaled by the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0 PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, and modulation enable are programmed by configuring the PLLFM register.

NOTE

While powering down the PLLs and if PLL0:PHI1 is used as the source for PLL1, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Configuring the appropriate MC_ME_<*mode*>_MC register to start PLL1 should only be done after PLL0 has achieved lock.

25.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

PLLDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)	32	R/W	See section	25.5.1/762
4	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)	32	R/W	See section	25.5.2/764
8	PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)	32	R/W	See section	25.5.3/766

28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset.

Table continues on the next page...

PLLDIG_PLL0SR field descriptions (continued)

Field	Description
	0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

25.5.3 PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. PLL0DV can be modified at anytime, but the changes become effective only after the PLL is disabled, then reenabled. If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or interrupt based on which is enabled. The reduced frequency divider bitfields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective when PLL0 is disabled, then reenabled.

Address: 0h base + 8h offset = 8h

PLLDIG_PLL0DV field descriptions

Field	Description
0 Reserved	This field is reserved.
1–4 RFDPHI1	PHI1 reduced frequency divider. This 4-bit field determines the VCO clock post divider for driving the PHI1 output clock. RFDPHI1 has a range of 4..15 (4h..Fh). All other values are reserved.
5–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16 Reserved	This field is reserved.
17–19 PREDIV	Input clock predivider. This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. The PREDIV value 000b causes the input clock to be inhibited. 000 Clock inhibit 001 Divide by 1 010 Divide by 2 011 Divide by 3 100 Divide by 4 101 Divide by 5 110 Divide by 6 111 Divide by 7
20–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 8...127 (8h...7Fh). All other values are reserved (see Clock configuration for details).

25.5.4 PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)

The PLL1CR is shown in the following table. It contains the operational state of PLL1, and is used to enable/disable PLL specific interrupts.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved

PLLDIG_PLL1DV field descriptions (continued)

Field	Description
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16–20 Reserved	This field is reserved.
21–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 16...34 (10h...22h). All other values are reserved.

25.5.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)

The PLL1FM register controls enables frequency modulation, and provides controls for modulation mode selection, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). The PLL would then be required to be power cycled to regain normal functionality.

Address: 0h base + 2Ch offset = 2Ch

PLLDIG_PLL1FM field descriptions (continued)

Field	Description
1 MODEN	Modulation enable. This bit enables the frequency modulation. 0 Frequency modulation disabled. 1 Frequency modulation enabled.
2 MODSEL	Modulation selection. This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Centre Spread Modulation - Modulation centred around nominal frequency. 1 Down Spread Modulation - Modulation spread below nominal frequency.
3–15 MODPRD	Modulation period. MODPRD is the modulation period variable derived from the formulas shown in Frequency modulation.
16 Reserved	This field is reserved.
17–31 INCSTP	Increment step. This field is the INCSTP variable derived from the formulas shown in Frequency modulation.

25.5.8 PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (PLL*n*CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 30h offset = 30h

Table continues on the next page...

PLLDIG_PLL1FD field descriptions (continued)

Field	Description
	0 Fractional divide disabled. 1 Fractional divide enabled.
2–13 Reserved	This field is reserved.
14–15 Reserved	Reserved. This field is reserved. **Important:** This field must be written 00b.
16–19 Reserved	This field is reserved.
20–31 FRCDIV	Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by the equation in the section Clock configuration.

25.6 Register classification for safety requirements

This module is classified as ViMo (Vital Modules) for functional safety. Hence, the registers of this module have been classified as shown in the Functional Safety chapter.

25.7 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

25.7.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for the PLL s are discussed in detail in the *Data Sheet*.

25.7.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{\text{pll0\_phi}} = f_{\text{pll0\_ref}} \times \left(\frac{\text{PLL0DV[MFD]}}{\text{PLL0DV[PREDIV]} \times \text{PLL0DV[RFDPHI]}} \right)$$

Equation 1. PLL0 PHI Output Frequency

$$f_{\text{pll0\_phi1}} = f_{\text{pll0\_ref}} \times \left(\frac{\text{PLL0DV[MFD]}}{\text{PLL0DV[PREDIV]} \times \text{PLL0DV[RFDPHI1]}} \right)$$

Equation 2. PLL0 PHI1 Output Frequency

$$f_{\text{pll1\_phi}} = f_{\text{pll1\_ref}} \times \left(\frac{\text{PLL1DV[MFD]} + \frac{\text{PLL1FD[FRCDIV]}}{2^{12}} + \frac{1}{2^{13}}}{2 \times \text{PLL1DV[RFDPHI]}} \right)$$

Equation 3. PLL1 PHI Output Frequency

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{\text{pll0\_VCO}} = \frac{f_{\text{pll0\_ref}} \times \text{PLL0DV[MFD]} \times 2}{\text{PLL0DV[PREDIV]}}$$

Equation 4. PLL0 VCO Frequency

$$f_{\text{pll1\_VCO}} = f_{\text{pll1\_ref}} \times \left(\text{PLL1DV[MFD]} + \frac{\text{PLL1FD[FRCDIV]}}{2^{12}} + \frac{1}{2^{13}} \right)$$

Equation 5. PLL1 VCO Frequency

NOTE

$f_{\text{pll0\_phi1}}$ is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of the PLL*n*DV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

Note

> The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_<*mode*>_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in Initialization information.

25.7.3 Loss of lock

The PLL digital interface registers provide the flexibility to select whether to generate an interrupt, assert system reset, or do nothing in the event that the PLL loses lock according to the available PLL*n*CR options.

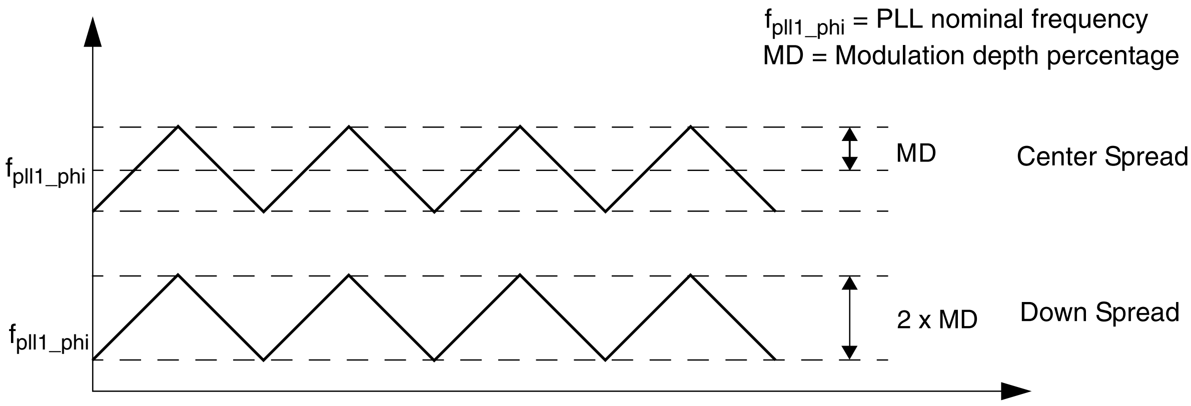
Loss of lock indication is only generated when the PLL is operating in normal mode.

The lock indication from the analog PLL is synchronized and stored in the status register. When the analog PLL loses lock or regains lock, it will be immediately indicated in the status register (after a synchronization time).

A pair of counters monitor the reference and feedback clocks to determine when the system has acquired frequency lock. Once the PLL has locked, the counters continue to monitor the reference and feedback clocks and report whether the PLL has lost lock. The lock status is indicated in the status register.

25.7.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in Figure 25-1. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].



f_{pll1_phi} = PLL nominal frequency
MD = Modulation depth percentage
f_{pll1_phi}
MD
Center Spread
f_{pll1_phi}
2 x MD
Down Spread

Figure 25-1. Triangular frequency modulation

> **NOTE**
>
> The device maximum operating frequency includes the frequency modulation. If center modulation is used, the f_{sys} must be below f_{max} by MD percentage such that $f_{max} = f_{sys} \times (1 + (MD\% / 100))$.

The following equations define how to calculate PLL1FM[MODPRD] and PLL1FM[INCSTP] based on the output frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD).

$$\mathrm{PLL1FM[MODPRD]} = \mathrm{round}\left(\frac{f_{\mathrm{pll1\_ref}}}{4 \times f_{\mathrm{mod}}}\right)$$

Equation 6. PLL1FM[MODPRD] Calculation

The equation to determine PLL1FM[INCSTP] is shown in Equation 7 on page 779.

$$\mathrm{PLL1FM[INCSTP]} = \mathrm{round}\left(\frac{(2^{15} - 1) \times \mathrm{MD} \times \mathrm{PLL1DV[MFD]}}{100 \times 5 \times \mathrm{PLL1FM[MODPRD]}}\right)$$

Equation 7. PLL1FM[INCSTP] Calculation

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

$$(\mathrm{PLL1FM[MODPRD]} \times \mathrm{PLL1FM[INCSTP]}) < 2^{15}$$

Equation 8. PLL1FM[MODPRD] and PLL1FM[INCSTP] Restriction

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is shown in Equation 9 on page 779.

$$\text{ModulationDepth} = \text{round}\left(\frac{\text{PLL1FM[MODPRD]} \times \text{PLLIFM[INCSTP]} \times 100 \times 5}{(2^{15} - 1) \times \text{PLL1DV[MFD]}}\right)$$

Equation 9. Modulation Depth

FM parameters should only be changed, and FM enabled, after PLL0 has obtained lock. The sequence for reprogramming the FM is:

1. Power down PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 0, followed by a mode change.
2. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].
3. Program the PLL1FM while PLL1 is powered down.
4. Power up the PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 1, followed by a mode change.
5. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].

25.8 Initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The Dual PLLDIG initialization procedure is described in the "Clocking" chapter.

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

Chapter 26
Clock Monitor Unit (CMU)

26.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take the necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

NOTE

See the "Clocking" chapter for the number of CMU instances on this chip.

26.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ $2^{CSR[RCDIV]}$ clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN ÷ 4.
- Event generation for various failures detected inside monitoring unit.

26.2 Block diagram

The block diagram of the CMU module(s) is shown in the “Clocking" chapter of this Reference Manual.

26.3 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 26-1. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.

Table continues on the next page...

Table 26-1. Signal description (continued)

Signal	I/O	Description
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

26.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

See "Clocking" chapter for register and field availability details.

CMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CMU Control Status Register (CMU_CSR)	32	R/W	See section	26.4.1/784
4	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	26.4.2/785
8	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	26.4.3/786
C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	26.4.4/786
10	CMU Interrupt Status Register (CMU_ISR)	32	w1c	See section	26.4.5/787
18	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	26.4.6/789

26.4.1 CMU Control Status Register (CMU_CSR)

Address: 0h base + 0h offset = 0h

* Notes:

- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 RCDIV	CLKMT0_RMN division factor.

Table continues on the next page...

CMU_CSR field descriptions (continued)

Field	Description
	These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0\_RMN} \div 2^{CMU\_CSR[RCDIV]}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4 11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

26.4.2 CMU Frequency Display Register (CMU_FDR)

The CMU_FDR is used to determine the measured frequency of:

- CLKMT0_RMN

with respect to the reference clock CLKMN0_RMT.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CMU_LFREFR field descriptions (continued)

Field	Description
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: (LFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

26.4.5 CMU Interrupt Status Register (CMU_ISR)

NOTE

All flags in the CMU_ISR are set asynchronously. This register must be read only after an interrupt(safe mode entry) is triggered by the CMU. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

NOTE

Before entering low-power stop modes, all clock frequency measurements in the CMU should be disabled. Failing to do so may result in spurious interrupts.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 Reserved	This field is reserved.
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than the high frequency reference value determined by CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than the low frequency reference value determined by CMU_LFREFR[LFREF], and CLKMN1 is 'ON' as signaled by the MC_ME. Software clears this field by writing a '1'. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. **NOTE:** When attempting to enter STOP mode with the chip running on the PLL, erroneous OLRI triggers may occur. To avoid this the XOSC should be stopped before entering STOP mode. 0 No OLR event 1 OLR event occurred

26.4.6 CMU Measurement Duration Register (CMU_MDR)

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												MD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

26.5 Functional description

26.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR[FD] as shown in the following equation:

$$f_{\mathrm{sel}} = f_{\mathrm{CLKMN0\_RMT}} \times \frac{\mathrm{CMU\_MDR[MD]}}{\mathrm{CMU\_FDR[FD]}}$$

26.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN ÷ $2^{\text{CMU\_CSR[RCDIV]}}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

$f_{\text{CLKMN0\_RMT}}$ must be greater than $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ by at least 0.5 MHz in order to guarantee correct $f_{\text{CLKMN0\_RMT}}$ monitoring.

26.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

An example of determining the $\text{HFREF}_{\text{Actual}}$ is as follows. Assume a $f_{\text{CLKMT0\_RMN}}$ = 16 MHz with a accuracy of +/-5%. In order to monitor a f_{CLKMN1} = 200 MHz, the ideal $\text{HFREF}_{\text{Ideal}}$ = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration ($\text{HFREF}_{\text{Actual}} = (\text{HFREF}_{\text{Ideal}} \div 0.95)$.

The actual LFREF value will be 762 when accuracy is taken into consideration ($LFREF_{Actual} = LFREF_{Ideal} \div 1.05$).

Chapter 27
Clock Generation Module (MC_CGM)

27.1 Introduction

27.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the chip blocks. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for details). A set of MC_CGM registers controls the clock dividers that are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources that have addressable memory spaces are accessed through the MC_CGM memory space.

The following figure is the MC_CGM block diagram.

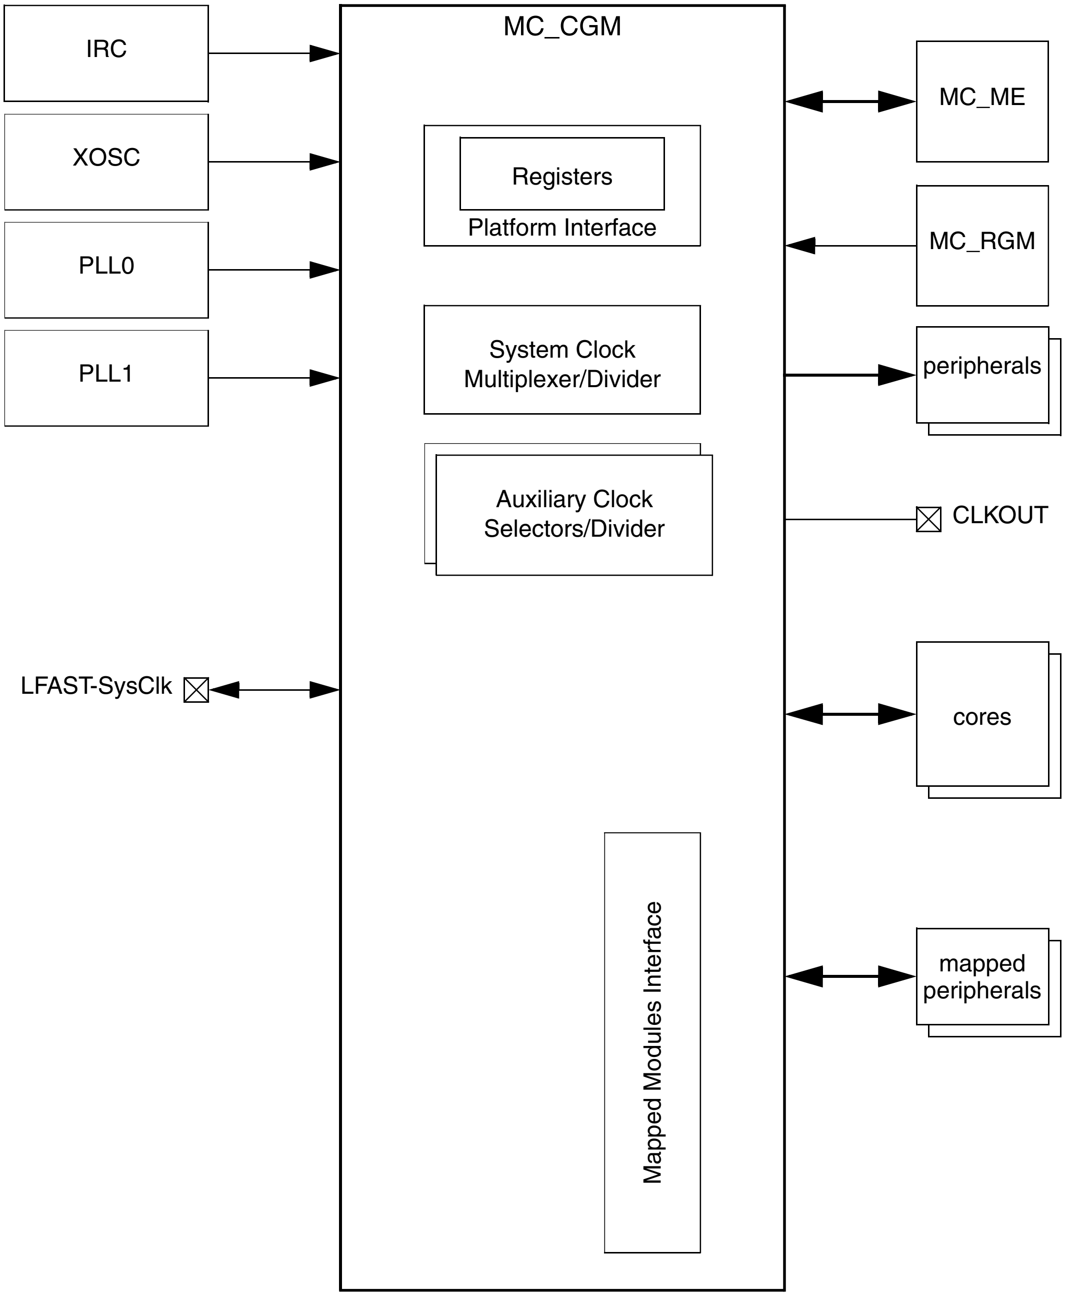

Figure 27-1. MC_CGM Block Diagram

27.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control

- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

27.2 External Signal Description

The MC_CGM delivers output clocks to the CLKOUT pin for off-chip use and/or observation.

The LFAST-SysClk pin can be either driven by the MC_CGM or used as an input to source the LFAST PLL clock.

27.3 Memory Map and Register Definition

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

MC_CGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
700	PCS Switch Duration Register (MC_CGM_PCS_SDUR)	8	R/W	See section	27.3.1/797

27.3.1 PCS Switch Duration Register (MC_CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See Progressive System Clock Switching for details on how to set this value.

This register is reset only on a power-on reset.

Address: 0h base + 700h offset = 700h

Bit	0	1	2	3	4	5	6	7
Read Write	SDUR							
Reset	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:

- Reset by POR only

MC_CGM_PCS_SDUR field descriptions

Field	Description
0–7 SDUR	Switch Duration This value defines the duration of one PCS clock switch step in terms of 16 MHz IRCOSC cycles.

27.3.2 PCS Divider Change Register 1 (MC_CGM_PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the 8-40 MHz XOSC on ramp-up and ramp-down, respectively. See Progressive System Clock Switching for details on how to set these values.

This register is reset only on a power-on reset.

NOTE

> Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 704h offset = 704h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MC_CGM_PCS_DIVC1 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value This is initial change value of the clock divider for the clock ramp-up phase when switching to the 8-40 MHz XOSC.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the 8-40 MHz XOSC.

27.3.3 PCS Divider End Register 1 (MC_CGM_PCS_DIVE1)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the 8-40 MHz XOSC on ramp-down. See Progressive System Clock Switching for details on how to set this value.

This register is reset only on a power-on reset.

NOTE

> Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 708h offset = 708h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SELSTAT	System Clock Source Selection Status - This value indicates the current source for the system clock.

Table continues on the next page...

MC_CGM_SC_SS field descriptions (continued)

Field	Description
	NOTE: If the current system clock source is the IRCOSC as reported in the MC_CGM System Clock Select Status Register (CGM_SC_SS[SELSTAT] = 0b0000) and Switch Trigger Cause shows the cause for the latest clock switch as a successful Mode Enter mode change (CGM_SC_SS[SWTRG] = 0b001) then the CGM_SC_SS[SWTRG] will incorrectly continue to show the cause for the latest clock switch as MC_ME succeeded after a SAFE mode request is generated. If a second SAFE mode request is generated then the CGM_SC_SS[SWTRG] switches to report the correct status value. If the CGM_SC_SS[SELSTAT] shows the system clock as IRCOSC, then software should check the Current Mode field of Mode Entry Global Status register (MC_ME_GS[S_CURRENT_MODE]) and the Safe mode Interrupt of Mode Entry Interrupt Status Register (MC_ME_IS[I_SAFE]) to establish the cause of the switch. 0000 16 MHz IRCOSC 0001 8-40 MHz XOSC 0010 PLL0 PHI 0011 reserved 0100 PLL1 PHI 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–14 SWTRG	Switch Trigger cause - This value indicates the cause for the latest clock source switch. 000 initial switch to 16 MHz IRCOSC due to power-on reset 001 switch after request from MC_ME succeeded 010 switch after request from MC_ME failed due inactive target clock 011 switch after request from MC_ME failed due inactive current clock 100 switch to 16 MHz IRCOSC due to SAFE mode request or reset succeeded 101 switch to 16 MHz IRCOSC due to SAFE mode request or reset succeeded, but current clock source was inactive 110 reserved 111 reserved
15 SWIP	Switch In Progress 0 clock source switching has completed 1 clock source switching is in progress
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27.3.12 System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)

This register controls system clock divider 0.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

WARNING

Use only odd DIV values (i.e., division factor of 2, 4, 6, 8, etc.). Even values will cause incorrect device behavior.

MC_CGM_SC_DC0 field descriptions

Field	Description
0 DE	Divider 0 Enable **NOTE:** Always write 0b1 to the DE bit when writing to any of the MC_CGM_SC_DCn registers. 0 Disable system clock divider 0 1 Enable system clock divider 0
1–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 DIV	Divider 1 Division Value — The resultant AIPS clock will have a period 'DIV + 1' times that of the system clock. If DE is set to '0' (divider 1 is disabled), any write access to the DIV field is ignored and the AIPS clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27.3.13 Auxiliary Clock 0 Select Control Register (MC_CGM_AC0_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 0 divider 0: motor control clock
- divided by auxiliary clock 0 divider 1: SGEN clock
- divided by auxiliary clock 0 divider 2: ADC clock

NOTE

PLL1 is routed on N15P devices into the AUX Clock Selector 0. It is recommended not to enable Frequency modulation on PLL1 when it is being used as a clock source for AUX Clock Selector 0.

See Figure 27-5 for details.

Address: 0h base + 800h offset = 800h

27.4 Functional Description

27.4.1 System Clock Generation

The following figure shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the 16 MHz IRCOSC as the system clock and to ignore the system clock select.

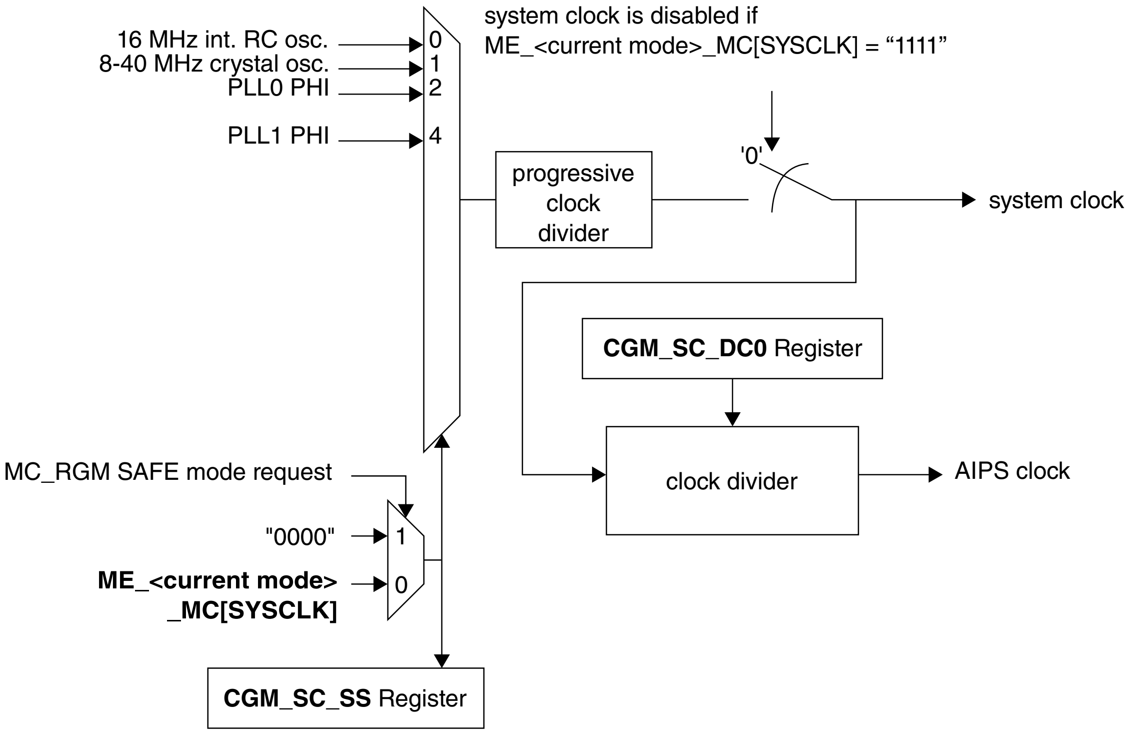

Figure 27-2. MC_CGM System Clock Generation Overview

27.4.1.1 System Clock Source Selection

During normal operation, the system clock selection is controlled

- on a SAFE mode or reset event, by the MC_RGM
- otherwise, by the MC_ME

27.4.1.2 Progressive System Clock Switching

Based on the power level values of the current and target modes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up. During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVEn registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVSn registers, where *n* corresponds to the target system clock source selection.

27.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in the following equation.

$$a_{\mathrm{max}} = \frac{f_{\mathrm{chg}}}{f_{\mathrm{src}}}$$

Equation 10

27.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of the 16 MHz internal RC oscillator. After the expiration of this time, the module changes the clock divider value, which changes the frequency of the system clock.

27.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the PCS_DIVCn[RATE] register is given in the following table.

Table 27-1. MC_CGM CGM_PCS_DIVC*n*[RATE] values

a_{max}	d	CGM_PCS_DIVC*n*[RATE]
0.05	0.012	12
0.10	0.048	48
0.15	0.112	112
0.20	0.184	184

27.4.1.2.4 Generic Clock Change Properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in the following equation.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16\text{MHz}}\right)}{d}} \right\rceil$$

Equation 11

27.4.1.2.5 Clock Ramp-Down

The clock ramp-down starts with the divider value 1 and with the given divider increment value PCD_DIVCn[RATE] and ends with the given divider value PCS_DIVEn[DIVE].

The divider end value for clock ramp-down is given in the following equation.

$$\text{PCS\_DIVEn}[\text{DIVE}] = \frac{f_{src}}{16\text{MHz}} \times 1000 - 1$$

Equation 12

Where f_{curr} is the frequency of the currently selected system clock source.

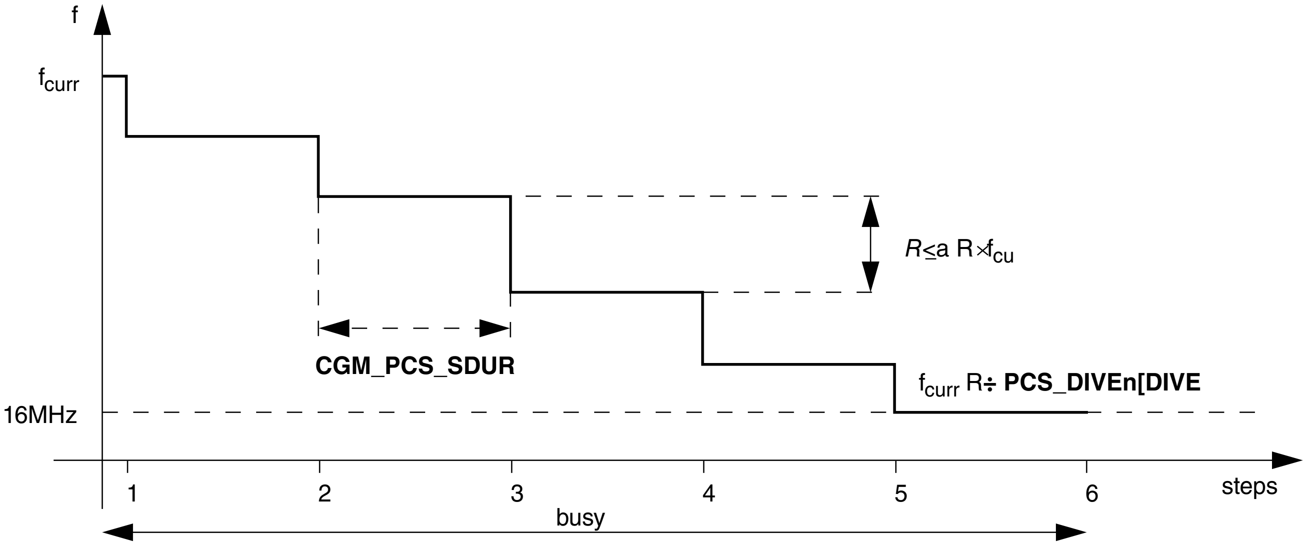

Figure 27-3. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

27.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value PCS_DIVSn[DIVS] and with the given divider decrement value PCD_DIVCn[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVCn[INIT] for system clock ramp-up is given in Equation 13 on page 829.

$$\text{PCS\_DIVC}n[\text{INIT}] = d \times k \times 1000$$

Equation 13

Where k is calculated from Equation 11 on page 828 using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in Equation 14 on page 829.

$$\text{PCS\_DIVS}n[\text{DIVS}] = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

Equation 14

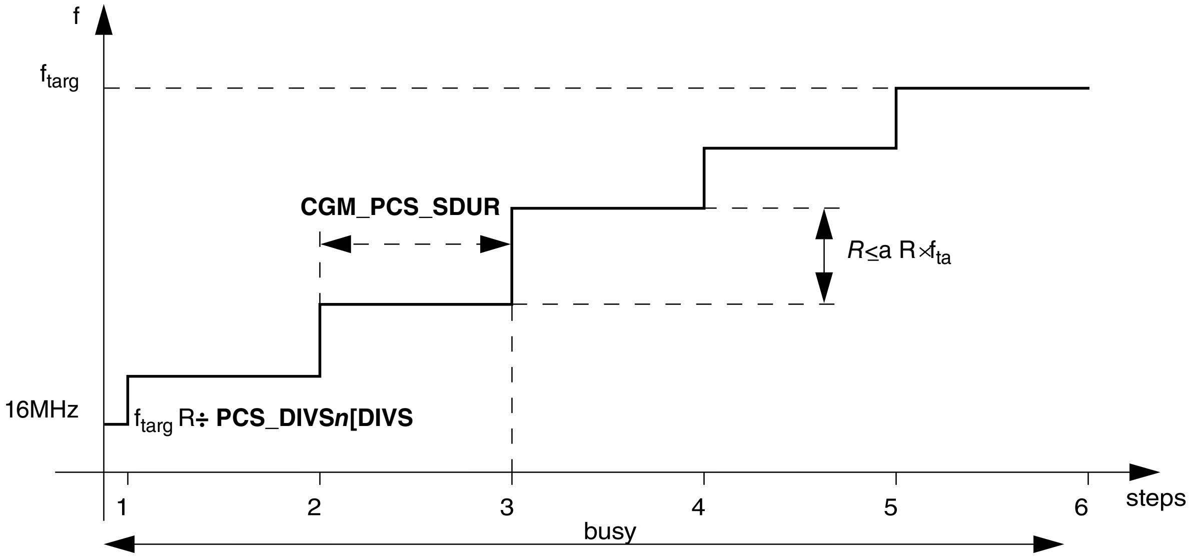

Figure 27-4. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

27.4.1.3 System Clock Disable

During the TEST mode, the system clock can be disabled by the MC_ME.

27.4.1.4 System Clock Dividers

The MC_CGM generates the following derived clock from the system clock:

- AIPS clock - controlled by the CGM_SC_DC0 register

27.4.2 Auxiliary Clock Generation

Figure 27-5 through Figure 27-11 show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- Auxiliary Clock 0 Select Control Register (MC_CGM_AC0_SC)
- Auxiliary Clock 3 Select Control Register (MC_CGM_AC3_SC)
- Auxiliary Clock 4 Select Control Register (MC_CGM_AC4_SC)
- Auxiliary Clock 5 Select Control Register (MC_CGM_AC5_SC)

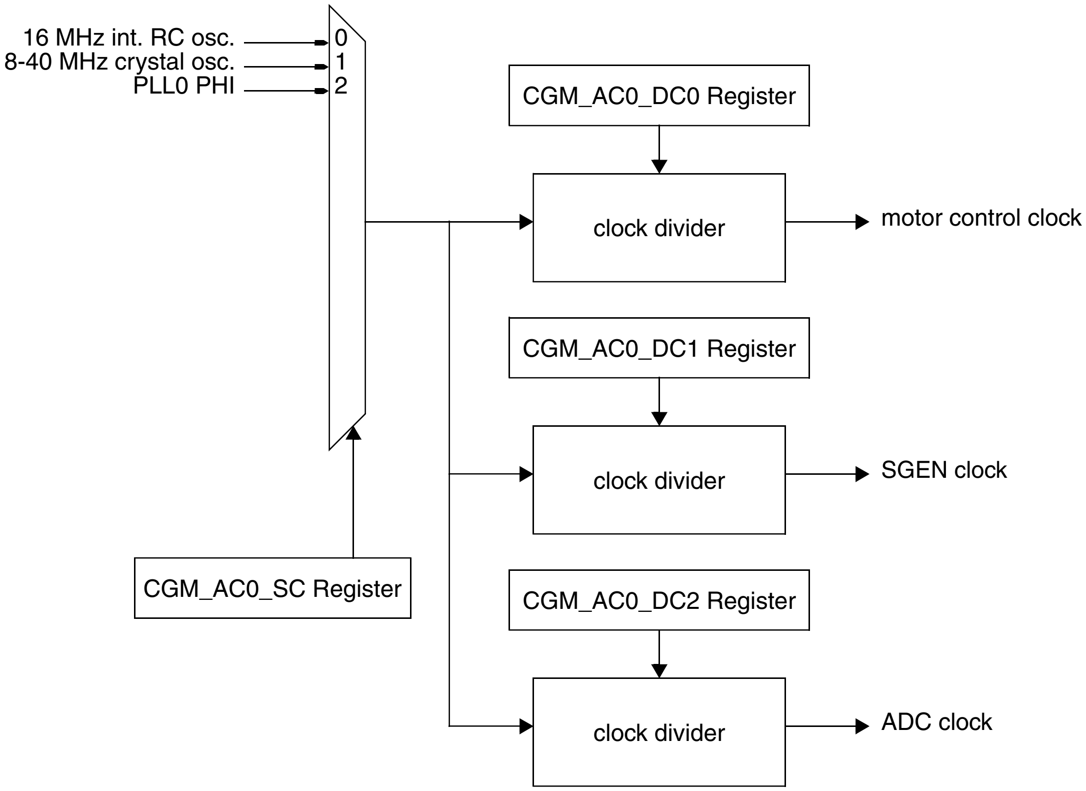

Figure 27-5. MC_CGM Auxiliary Clock 0 Generation Overview

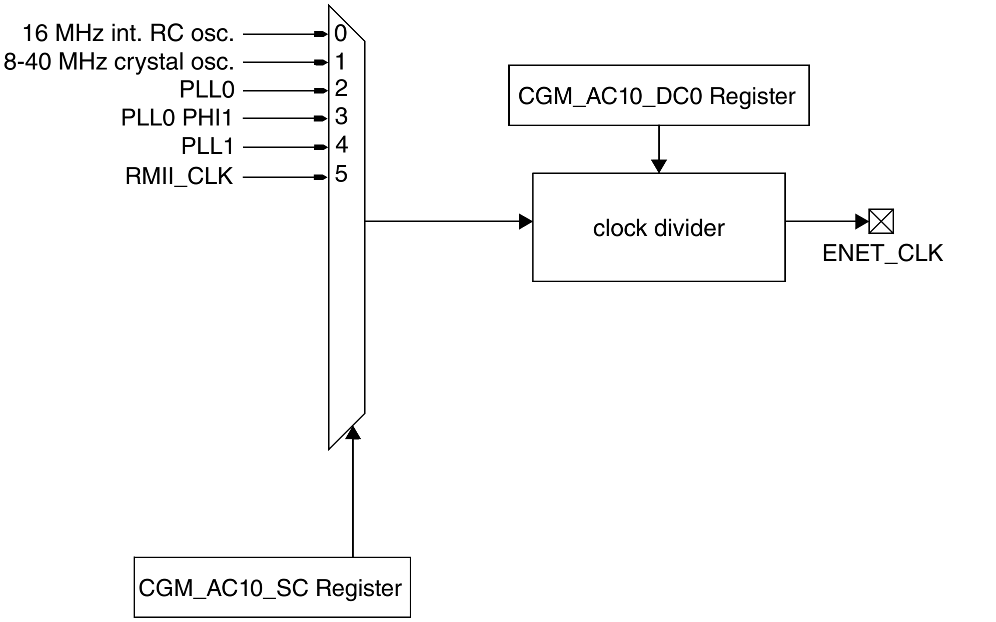

Figure 27-12. MC_CGM Auxiliary Clock 10 Generation Overview

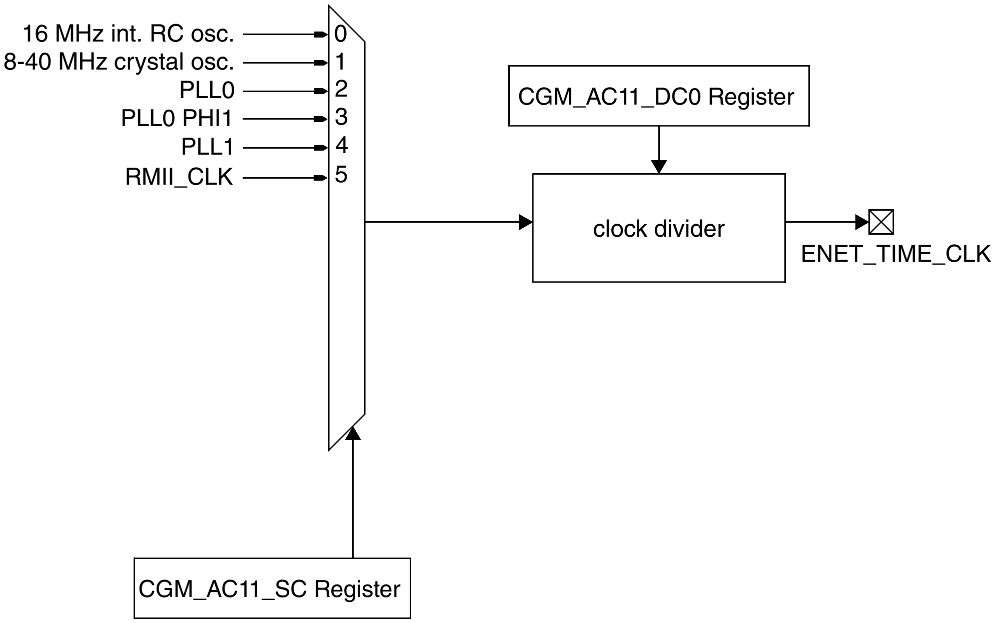

Figure 27-13. MC_CGM Auxiliary Clock 11 Generation Overview

27.4.2.1 Auxiliary Clock Dividers

The MC_CGM generates the following derived clocks:

- Motor Control clock - controlled by the **CGM_AC0_DC0** register
- SGEN clock - controlled by the **CGM_AC0_DC1** register
- ADC clock - controlled by the **CGM_AC0_DC2** register
- FlexRay clock - controlled by the CGM_AC1_DC0 register
- SENT clock - controlled by the CGM_AC1_DC1 register
- CAN clock - controlled by the CGM_AC2_DC0 register
- LFAST PLL clock - controlled by the CGM_AC5_DC0 register
- CLKOUT pin clock - controlled by the CGM_AC6_DC0 register
- ENET clock - controlled by the CGM_AC10_DC0 register
- ENET TIME clock - controlled by the CGM_AC11_DC0 clock register

27.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)
- Auxiliary Clock 0 Divider 0 Configuration Register (MC_CGM_AC0_DC0)
- Auxiliary Clock 0 Divider 1 Configuration Register (MC_CGM_AC0_DC1)
- Auxiliary Clock 0 Divider 2 Configuration Register (MC_CGM_AC0_DC2)
- Auxiliary Clock 1 Divider 0 Configuration Register (MC_CGM_AC1_DC0)
- Auxiliary Clock 1 Divider 1 Configuration Register (MC_CGM_AC1_DC1)
- Auxiliary Clock 2 Divider 0 Configuration Register (MC_CGM_AC2_DC0)
- Auxiliary Clock 5 Divider 0 Configuration Register (MC_CGM_AC5_DC0)
- Auxiliary Clock 6 Divider 0 Configuration Register (MC_CGM_AC6_DC0)
- Auxiliary Clock 10 Divider 0 Configuration Register (MC_CGM_AC10_DC0)
- Auxiliary Clock 11 Divider 0 Configuration Register (MC_CGM_AC11_DC0)

The reset value of all counters is '1'. If a divider has its DE bit in the respective configuration register set to '0' (the divider is disabled), any value in its DIV field is ignored.

Chapter 28
OSC Digital Interface (XOSC)

28.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provide the register interface for the programmable features. Selection of the XOSC as a source clock is controlled by the Clock Generation Module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry Module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control
- Crystal oscillator mode selection
  - Loop Controlled Pierce Mode (LCP)
  - Full Swing Pierce Mode (FSP)

28.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that is used as an input to the PLLs and can be selected as the reference clock for many of the peripherals on the device.

The table below shows the possible configurations of the XOSC.

Table 28-1. XOSC configurations

OSC EN (from MC_ME)	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC Output	XOSC MODE
0	0	Crystal, or left opened	Crystal, or left opened	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

28.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see “Mode Entry Module (MC_ME)” chapter). The ME_<*mode*>_MC[XOSCON] controls the power down of oscillator based on the current device mode (see “MC_ME Memory Map” table for available *modes*). The status of the XOSC is shown in the MC_ME_GS[S_XOSC].

28.2.2 Oscillator startup delay

A bit in the UTEST flash memory determines whether the analog portion of the oscillator is enabled at powerup. If enabled, the analog portion of the oscillator is powered-up during Phase3 of the device reset sequence (pre-self-test sequence). In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL0).

The default value for this field after reset depends on implementation and can be found in the XOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note

It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

28.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

28.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software and is only cleared by a system reset. In bypass mode, the oscillator is disabled and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

NOTE

The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

NOTE

Power down from the MC_ME will have no effect on the oscillator. The bypass clock will continue running in the device. It is ensured that mode transitions from the MC_ME complete successfully by providing bypass information to the MC_ME.

28.2.5 Crystal oscillator mode selection

There are two oscillator mode selections possible, Full Swing Pierce mode and Loop Controlled Pierce mode. The operating mode is selected by configuring the XOSC_CTL[OSCM].

28.2.5.1 Loop Controlled Pierce mode

Loop Controlled Pierce mode (LCP) is the default oscillator mode. LCP has the following attributes:

- Provides a smaller frequency range

- Limits the amplitude of the crystal oscillation utilizing Amplitude Loop Control (ALC)
- Reduced EMI
- Reduced power consumption
- Shorter settling time
- Crystal is exposed to reduced stress since the amplitude is reduced
- Reduced number of external components, feedback resistor already integrated

28.2.5.2 Full Swing Pierce mode

Full Swing Pierce mode (FSP) has the following attributes when compared with LCP:

- Provides a wider frequency range
- Less susceptible to noise
- The crystal amplitude is rail-to-rail
  - Distorted oscilation with several harmonics
  - Increased EMI
- Slower settling time
- Feedback resistor and 300 ohms of current limitation are already integrated.

NOTE

> Consult with crystal supplier to determine the need of extra resistance in XTAL to avoid crystal overdrive.

28.3 Memory map and register definition

XOSC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

XOSC_CTL field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.

Table continues on the next page...

XOSC_CTL field descriptions (continued)

Field	Description
1 OSCM	Crystal Oscillator Mode. This bit selects the oscillator mode when not in bypass. 0 FSP mode (full swing pierce mode) 1 LCP mode (loop controlled pierce mode)
2 MON	XOSC clock monitor enable. 0 Monitoring is disabled. 1 Monitoring is enabled.
3–7 Reserved	This field is reserved.
8–15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV × 512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24 I_OSC	Crystal oscillator clock interrupt This bit is set by hardware when OSCCNT counter reaches the count value EOCV x 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.
25–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Chapter 29
IRCOSC Digital Interface

29.1 Introduction

The Internal RC Oscillator Digital Interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

29.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see the Data Sheet for timing details) which is required for stabilization. The IRCOSC status is updated in the MC_ME_GS[S_IRC] field (see the "Mode Entry Module MC_ME" chapter).

The IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

29.3 Memory map and register definition

IRCOSC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	IRCOSC Control Register (IRCOSC_CTL)	32	R/W	See section	29.3.1/844

29.3.1 IRCOSC Control Register (IRCOSC_CTL)

The IRCOSC_CTL contains user programmable parameters.

IRCOSC_CTL is writable only in supervisor mode.

IRCOSC_CTL field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This bit can be written with any value, but writes are ignored. A read returns last written value.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 USER_TRIM	User trimming bits with respect to nominal factory frequency The MSB of the USER_TRIM bits is used to determine whether the frequency will be increased or decreased. If MSB = 0 then a change in USER_TRIM[3:0] will decrease the frequency, and likewise, if MSB = 1 then a change in USER_TRIM[3:0] will increase the frequency. Frequency trimming calculation shows how RCOSC_CTL[USER_TRIM] field is used to trim the IRCOSC frequency.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

IRCOSC_CTL field descriptions (continued)

Field	Description
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This field may sometimes have the value of 1, and can be cleared by writing a 1 to this bit. However, this field has no effect on the IRCOSC or chip behavior.
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.3.2 Frequency trimming calculation

Table 29-1. IRCOSC_CTL[USER_TRIM] frequency trimming calculation

USER_TRIM[4:0] value	Frequency
....	....
10011	$f + (3 \times \delta f_{TRIM})$
10010	$f + (2 \times \delta f_{TRIM})$
10001	$f + \delta f_{TRIM}$
10000	f
00000	f
00001	$f - \delta f_{TRIM}$
00010	$f - (2 \times \delta f_{TRIM})$
00011	$f - (3 \times \delta f_{TRIM})$
....	....

NOTE

See the data sheet for δf_{TRIM} value and min/max frequency variations.

Chapter 30
RAM Controller (PRAMC)

30.1 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. Shown below in Figure 30-1 is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

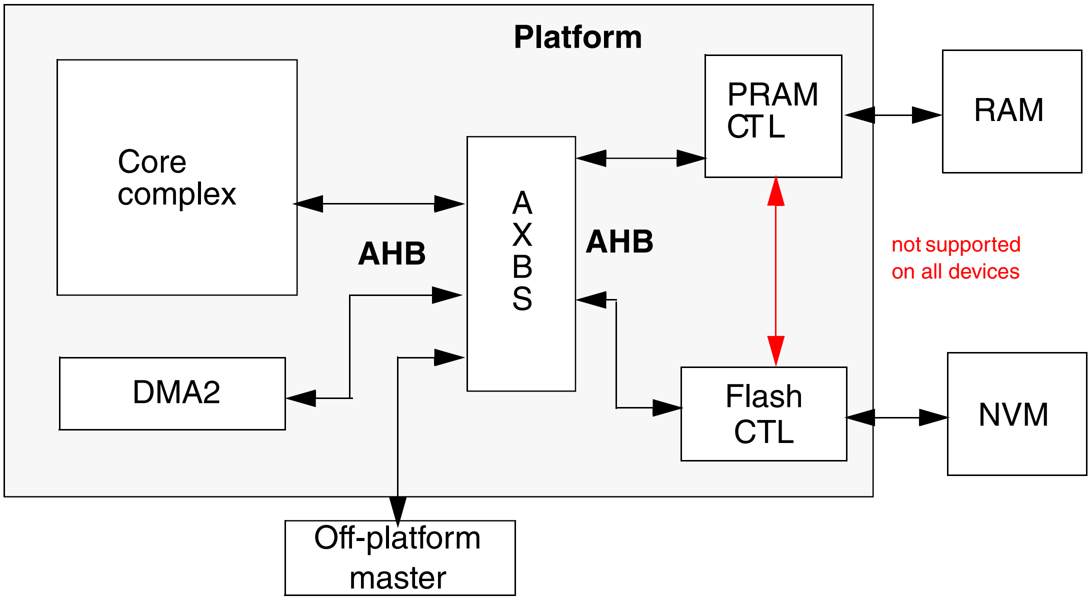

Figure 30-1. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

30.2 SRAM controller memory map and register definition

The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

NOTE

Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

PRAMC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

PRAMC_PRCR1 field descriptions (continued)

Field	Description
22–23 PRI	AHB port arbitration mode. Use this register to select the AHB port arbitration mode. 00 Round Robin arbitration is selected. 01 Port p0 has priority over port p1. 10 Port p1 has priority over port p0. 11 Reserved.
24 P1_BO_DIS	Port p1 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
25 P0_BO_DIS	Port p0 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FT_DIS	Flow through disabled. This field defines the AHB response on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. **NOTE:** Do not change the FT_DIS bit value while accessing system RAM. Relocate code programming the FT_DIS bit to another memory area, e.g., local core memory. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

30.3 Functional description

This section describes the functions of the RAM controller.

30.3.1 Read and Write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

30.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

30.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency.

30.3.2 Writes

This section discusses various write operations of the RAM controller.

30.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

30.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. Figure 30-2 provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to Reliability considerations.

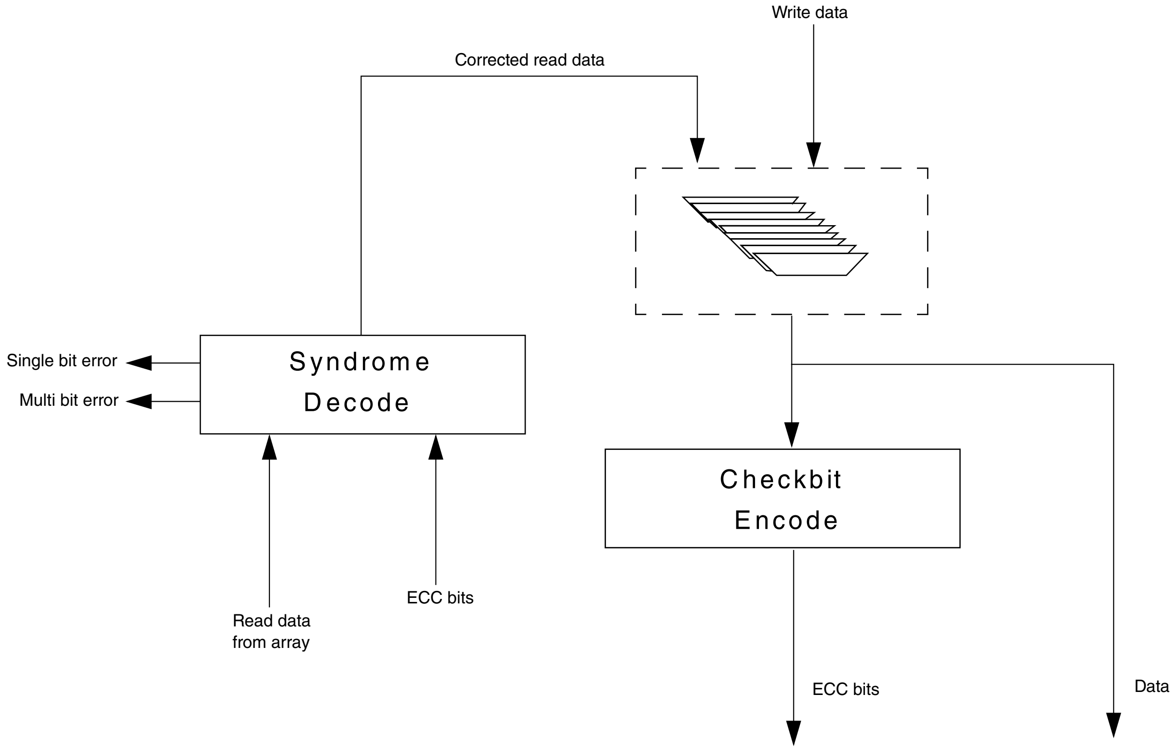

Figure 30-2. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

30.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

30.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

30.5 Reliability considerations

This section discusses reliability considerations of the RAM controller.

30.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit.*

Table 30-1. RAM controller basic H-matrix definition

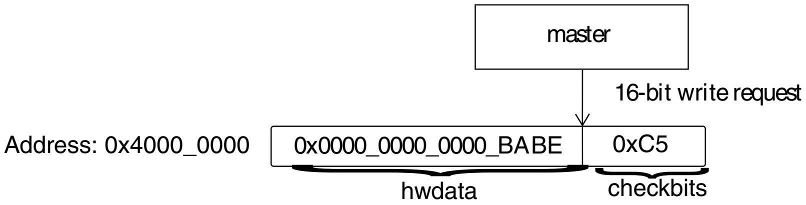
30.5.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:

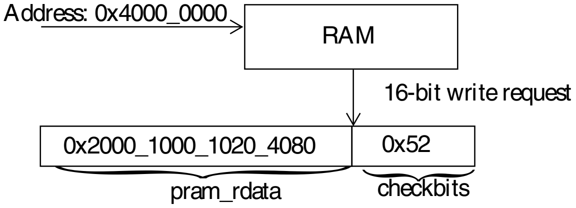
- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

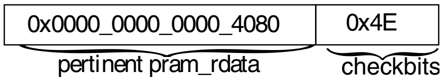


- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

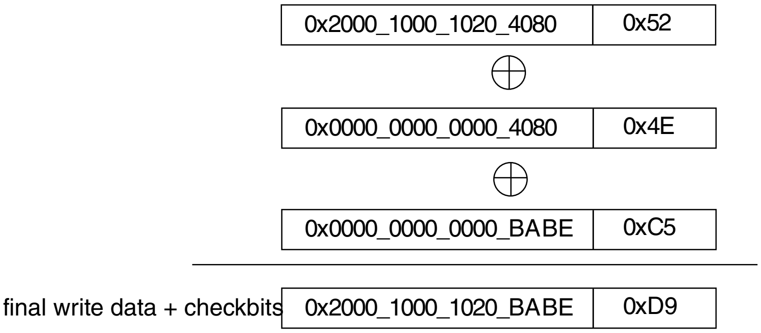
  If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.



- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.



- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.



This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

30.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions:

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor also verifies the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

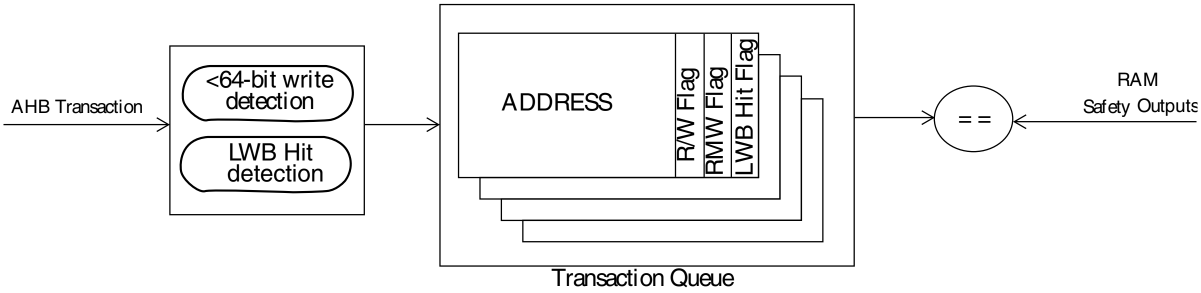


Figure 30-3. RAM controller transaction monitor block diagram

Chapter 31
Flash Memory Controller (PFLASH)

31.1 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to on-chip System RAM that can be used as overlay RAM.

The flash memory controller supports one 64-bit AHB bus and a 256-bit read data interface from each flash memory array. The AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. The mini-cache entry is 256 bits in size, matching the flash array page size and providing 256 bytes of total buffered storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

31.2 Features

The following list summarizes the key features of the flash memory controller:

- One 64-bit AHB interface port (p0) allowing access to dedicated prefetch mini-cache.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.

- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip system RAM

31.4 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configurationand overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario. There is no idle indicator for the flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the flash, code execution must be temporarily moved to system RAM.

PFLASH_PFCR1 field descriptions

Field	Description
0 P0_M15PFE	Port0 Master 15 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 15. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
1 P0_M14PFE	Port0 Master 14 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 14. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
2 P0_M13PFE	Port0 Master 13 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 13. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
3 P0_M12PFE	Port0 Master 12 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 12. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
4 P0_M11PFE	Port0 Master 11 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 11. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
5 P0_M10PFE	Port0 Master 10 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 10. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
6 P0_M9PFE	Port0 Master 9 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 9. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
7 P0_M8PFE	Port0 Master 8 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 8. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
8 P0_M7PFE	Port0 Master 7 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 7. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
9 P0_M6PFE	Port0 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P0_M5PFE	Port0 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
11 P0_M4PFE	Port0 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. A value of '1' in the most significant bit causes the flash controller to function in retrograde/legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1xx Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. Higher operating frequencies require non-zero settings for this field for proper flash operation. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet. This field applies to the configuration of Port0. 0000 No additional wait-states are added 0001 One additional wait-state is added ... 1111 Fifteen additional wait-states are added
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BFEN_LK]=0. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

31.4.2 Platform Flash Configuration Register 3 (PFLASH_PFCR3)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PFLASH_PFCR3 field descriptions

Field	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set acrosstwo ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 BFEN_LK	BFEN Lock. This field controls access to the PFCR2[P0_BFEN] field, which enables or disables line read buffer hits and isare also used to invalidate the buffers. 0 The PFCR2[P0_BFEN] field is R/W. 1 PFCR2[P0_BFEN] field is Read-only.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.4.3 Platform Flash Access Protection Register (PFLASH_PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

NOTE

See the chip-specific platform flash controller information for details about the actual masters available on the device.

PFLASH_PFAPR field descriptions (continued)

Field	Description
14–15 M7AP	Master 7 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
16–17 M8AP	Master 8 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
18–19 M9AP	Master 9 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
20–21 M10AP	Master 10 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
22–23 M11AP	Master 11 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
24–25 M12AP	Master 12 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
26–27 M13AP	Master 13 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

Table continues on the next page...

PFLASH_PFAPR field descriptions (continued)

Field	Description
28–29 M14AP	Master 14 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
30–31 M15AP	Master 15 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

31.4.4 Platform Flash Remap Control Register (PFLASH_PFCRCR)

The PFCRCR is used to globally enable/disable the calibration remap function.

CAUTION

Overlay remap functions, when used with line read buffers enabled (PFLASH_PFCRx[BFy_EN] field(s)='1') have a potential to cause data coherency issues, i.e., prefetched data in a line read buffer can become out-of-sync with data contained at the associated flash address range. To prevent this issue, always clear the flash controller line read buffers prior to enabling any remap region.

To clear the flash controller line read buffers, issue an interlock write command to a valid flash memory address. There will not be an actual flash program operation performed, but the flash controller mini-cache will be cleared as a side effect of executing the command. The interlock write must be issued from a core having appropriate access to flash. The sequence is as follows:

1. Set the C55FMC_MCR[PGM] field to '1'
2. Issue a 64-bit write to a valid flash address on a 64-bit boundary, i.e., the least significant 5 bits of the address are '0'
3. Clear C55FMC_MCR[PGM]

Address: 0h base + 10h offset = 10h

PFLASH_PFCRCR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 8 to 4. This field is initialized by hardware reset. 1 Established calibration overlay regions are considered safety-critical. 0 Established calibration overlay regions are not considered safety-critical.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remapping evaluation on system flash accesses. This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

31.4.5 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 8 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Address: 0h base + 14h offset = 14h

PFLASH_PFCRDE field descriptions

Field	Description
0 CRD0EN	Calibration Remap Descriptor 0 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 0 invalid 1 Calibration Remap Descriptor 0 valid
1 CRD1EN	Calibration Remap Descriptor 1 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 1 invalid 1 Calibration Remap Descriptor 1 valid
2 CRD2EN	Calibration Remap Descriptor 2 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset.

Table continues on the next page...

PFLASH_PFCRDE field descriptions (continued)

Field	Description
	0 Calibration Remap Descriptor 2 invalid 1 Calibration Remap Descriptor 2 valid
3 CRD3EN	Calibration Remap Descriptor 3 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 3 invalid 1 Calibration Remap Descriptor 3 valid
4 CRD4EN	Calibration Remap Descriptor 4 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 4 invalid 1 Calibration Remap Descriptor 4 valid
5 CRD5EN	Calibration Remap Descriptor 5 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 5 invalid 1 Calibration Remap Descriptor 5 valid
6 CRD6EN	Calibration Remap Descriptor 6 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 6 invalid 1 Calibration Remap Descriptor 6 valid
7 CRD7EN	Calibration Remap Descriptor 7 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor 7 invalid 1 Calibration Remap Descriptor 7 valid
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.4.6 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 100h offset + (16d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PFLASH_PFCRD*n*_Word0 field descriptions

Field	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.4.7 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region.

The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 104h offset + (16d × i), where i=0d to 7d

PFLASH_PFCRD*n*_Word1 field descriptions

Field	Description
0–27 PSTARTADDR	Calibration Remap Descriptor *n* Physical Start Address - This field defines the most significant bits of the 0-modulo-size physical start byte address of the calibration remap descriptor. This address corresponds to the physical address which maps to the destination calibration overlay memory. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.4.8 Platform Flash Calibration Region Descriptor n Word2 (PFLASH_PFCRD*n*_Word2)

The third word of the calibration region descriptor defines a per-master calibration remap enable and the remap region size. For cacheable spaces being remapped, the minimum region size is 32 bytes to match the flash page and cache line sizes. Writes to this word clear the calibration remap descriptor's valid bit.

Address: 0h base + 108h offset + (16d × i), where i=0d to 7d

31.5 Functional description

The flash memory controller interfaces between:

- The AHB system bus port
- Flash memory array
- System RAM

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

31.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

31.5.2 Access protections

On-chip Flash memory accesses are subject to restrictions based on chip security implementation and/or requirements based on functional restrictions of the flash memory, e.g., a read access to a flash block while it is currently being written is not allowed. When a prohibited access is attempted, a system bus error termination results.

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding read access control or write access control settings do not allow the access, thus causing a protection violation. See Platform Flash Access Protection Register (PFLASH_PFAPR) for more detail. In this case the flash memory controller does not initiate the requested flash array access.
- Attempted access by an AHB master to a flash region where the corresponding censorship control is asserted.
- The flash returns an error response on an attempted access to a partition that is unavailable. (see Flash error response operation or Embedded Flash Memory).
- Attempted access by an AHB master to a reserved region in the flash memory map.

The flash array may also signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

31.5.2.1 Censorship

The flash space is defined by regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- UTEST flash

Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

31.5.2.2 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in Platform Flash Access Protection Register (PFLASH_PFAPR). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

31.5.3 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

NOTE

> Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

31.5.4 Line read buffers and prefetch operation

The AHB ports of the flash memory controller contains a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see Platform Flash Configuration Register 1 (PFLASH_PFCR1)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

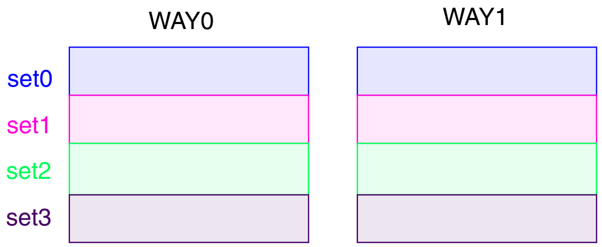

Figure 31-2. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in Platform Flash Configuration Register 1 (PFLASH_PFCR1). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR1[P0_BFEN] must be set to ‘1’,

2. PFCR1[P0_PFLIM] must be non-zero, and
3. Either PFCR1[P0_IPFEN] or PFCR1[P0_DPFEN] must be asserted.

Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

31.5.5 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls. Prefetches are never triggered by write cycles.

31.5.6 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

31.5.7 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration (P0_WCFG) field. Refer to Platform Flash Configuration Register 3 (PFLASH_PFCR3). The buffers can be organized as a "pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

31.5.8 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to on-chip System RAM that can be used as overlay RAM.

The overlay function supports the following features:

- Can be mapped over internal flash memory
    - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces

- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash
    - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function :
    - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
    - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay targets:

- A portion of the system RAM can be used for overlay.

31.5.8.1 PFlash calibration remap to RAM

The overlay RAM is selected based on the translated physical address.

The translated physical address defines the destination memory. Table 31-1 shows the base addresses for the calibration data memories as defined by the system memory map.

Table 31-1. Calibration data memory base addresses

Calibration Memory	Base Address	Possible Access Sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address.

The read data interface of system RAM is 64 bits wide , whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(\mathrm{RWSC}+2)\geq\left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}+2\right)\geq(\mathrm{OverlayRAMTransferBurstLatency})$$

Equation 15. Access time

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150 °C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD*n*) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries.

The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to determine the region "hit". The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region "hit" data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

31.5.9 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

31.5.9.1 e2eECC End-to-End ECC

31.5.9.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

   addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

   addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

   Before performing the interlock write to the flash array, the flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

   fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

   addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

31.5.9.2 Flash address generation check

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

31.5.9.2.1 Overlay RAM feedback check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

31.5.9.2.2 Reliability considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming PFCRCR[SAFE_CAL]=1, the flash memory controller treats the set of available calibration region descriptors as a replicated pair, with each set containing half the total number of available calibration region descriptors.

If there are 32 calibration region descriptors, CRD0 – CRD31, and PFCRCR[SAFE_CAL]=1, the flash memory controller treats CRD0 – CRD15 and CRD16 – 32 as replicated sets of 16 calibration region descriptors, where:

- CRD0 and CRD16 are configured identically
- CRD1 and CRD17 are configured identically
- CRD2 and CRD18 are configured identically
- ...
- and CRD15 and CRD31 are configured identically

Expressed more generally, the contents of CRD[*n*] must be identical to the contents of CRD[(N/2) + *n*], where N is the total number of region descriptors and 0 ≤ *n* ≤ (N/2) – 1.

Note

> It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2) – 1] and the calibration regions defined in CRD[N/2] to CRD[N – 1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

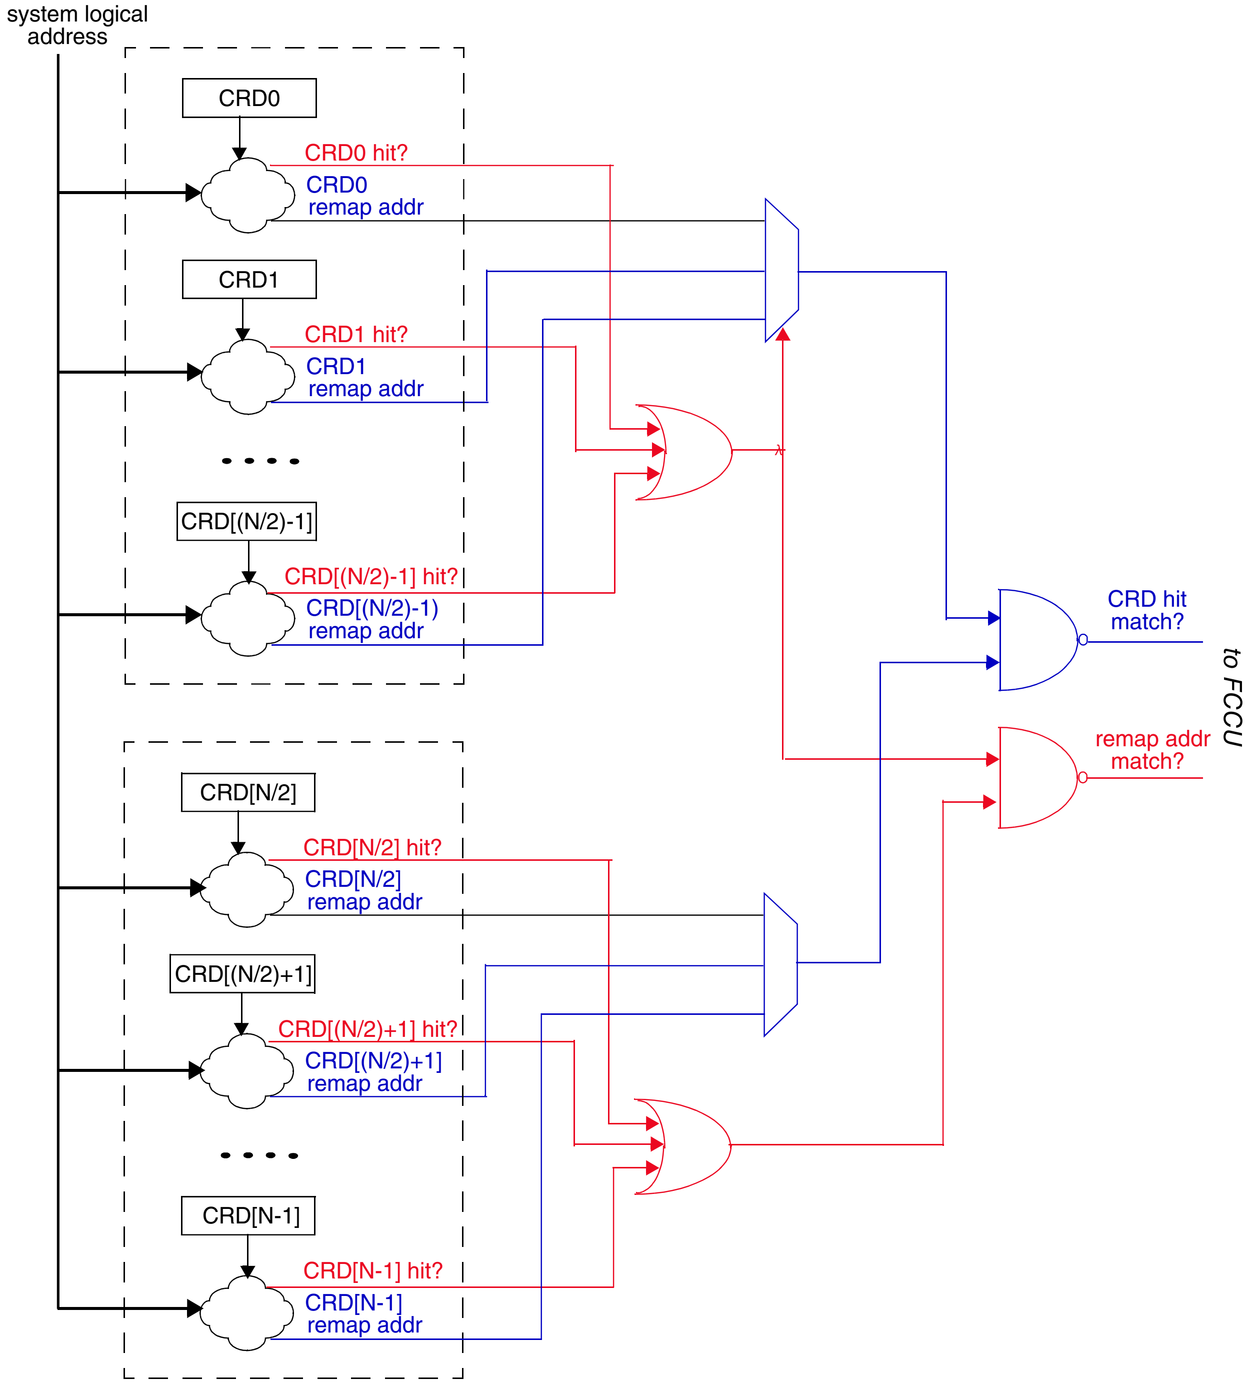

Figure 31-3. Safety-critical calibration remap datapath with redundancy

31.5.10 ECC on data flash accesses

ECC events detected on accesses to data flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU. For non-correctable error detection, the flash memory controller returns a value of FFFF_FFFFh to the requesting master.

NOTE

EEPROM should be avoided for storage of executable code.

31.5.11 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

Chapter 32
Embedded Flash Memory (c55fmc)

32.1 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

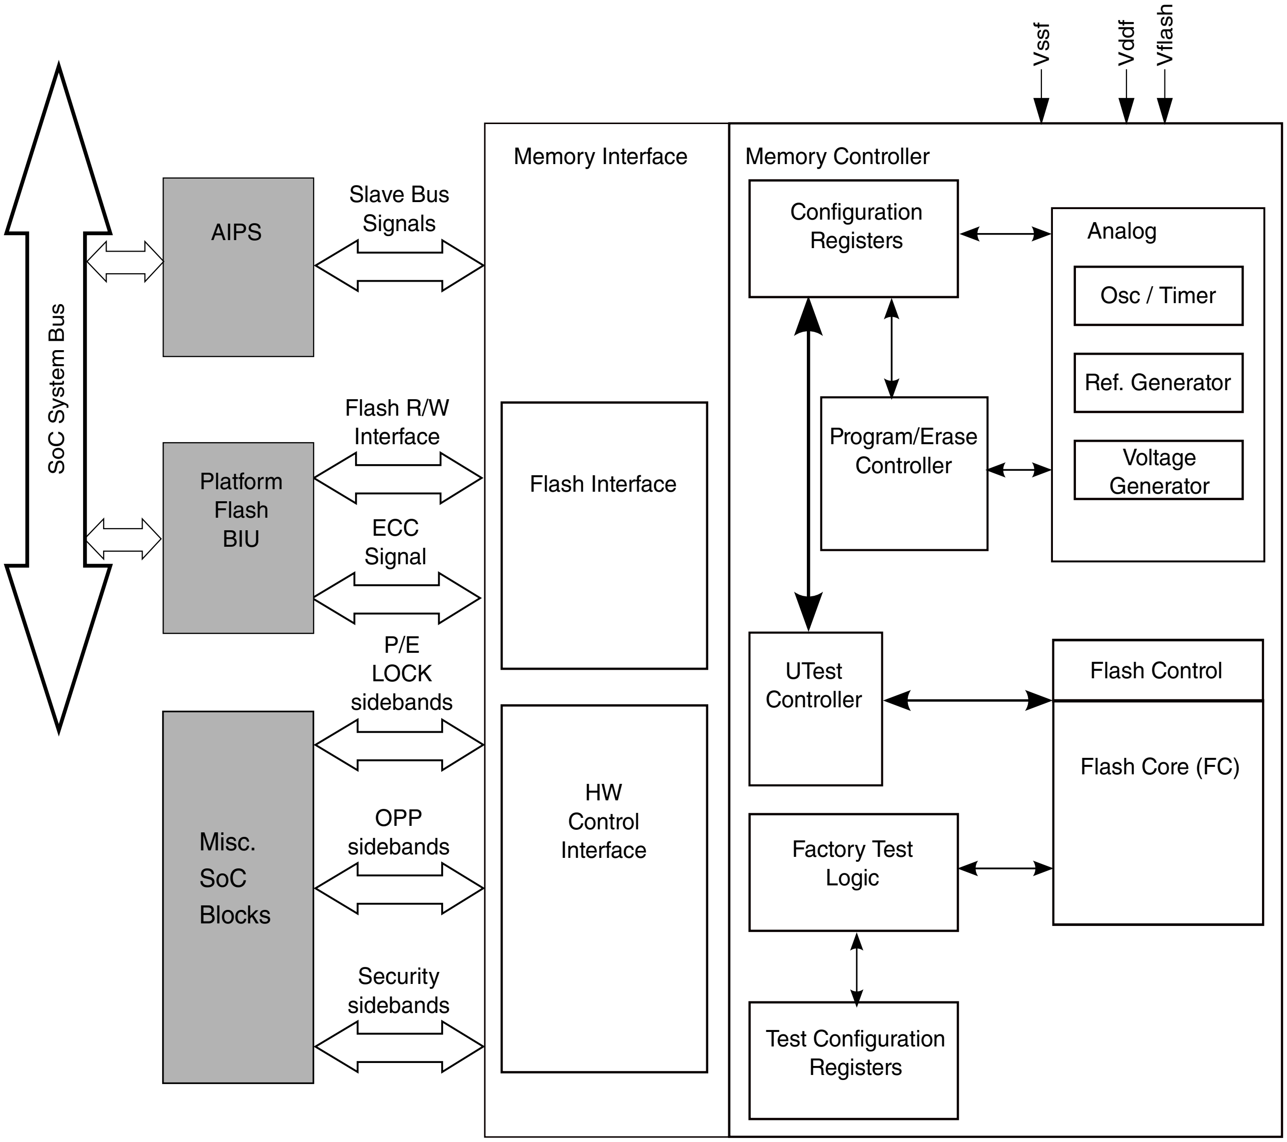

Figure 32-1. c55fmc block diagram

32.1.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see Functional Description.

32.1.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

32.1.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *Low power mode* turns off all DC current sources within the embedded flash memory on the Vflash domain, and enables VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in low power mode.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

32.2 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

32.3 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks..

32.3.1 Module Configuration Register (C55FMC_MCR)

NOTE

1. A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional Description.
2. See Functional Description for information about simultaneous MCR writes, and priority levels.

C55FMC_MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.
17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 A read-while-write error occurred during a previous read.
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections. 1 A Single Bit Correction occurred during a previous read.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations. The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. **NOTE:** This bit transitions from a 0 to 1 during reset and remains at 1 after reset. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEG	Program/Erase Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. **NOTE:** 1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block. 2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation. 0 Program or erase operation failed. 1 Program or erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set. 1 An interrupt request will be generated when the DONE flag is set.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: • User mode read (ERS is low and UTE is low) • Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within Tesus of this transition. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: • Erase (ERS = 1, ESUS = 0) • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. **NOTE:** Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

32.3.2 Extended Module Configuration Register (C55FMC_MCRE)

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 8h offset = 8h

* Notes:

- The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_MCRE field descriptions

Field	Description
0 HT	High Temperature Enabled. HT provides configuration information of the module. If the flash is tuned for high temperature operation (165 °C) at reduced performance (slower read at 165 °C and less and slower program and erase at 150 °C or less), and limited features at this temperature (no margin reads), the HT status bit will be a 1. Default is 150 °C as maximum operating temperature, and the HT status bit will be a 0. HT is read only. 0 150 °C maximum operating temperature. 1 165 °C maximum operating temperature with reduced performance.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 n256K	Number of 256 KB blocks. The value of this field is dependent upon the size of the embedded flash memory. This field is read only. 00000 Zero 256 KB blocks. 00001 Two 256 KB blocks (512 KB total). 00010 Four 256 KB blocks (1 MB total). 00011 Six 256 KB blocks (1.5 MB total). 00100 Eight 256 KB blocks (2 MB total). 00101 Ten 256 KB blocks (2.5 MB total).

32.3.3 Lock 0 register (C55FMC_LOCK0)

The Lock 0 (LOCK0) register provides a means to protect blocks from being modified.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	TSLOCK	0	LOWLOCK													
W		▨														
Reset	1	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	MIDLOCK															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

C55FMC_LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended.

Table continues on the next page...

C55FMC_LOCK0 field descriptions (continued)

Field	Description
	0 UTest NVM block is available to be programmed. 1 UTest NVM block is locked and cannot be programmed.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations
16–31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

32.3.4 Lock 1 register (C55FMC_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–15 Reserved	This field is reserved. Reserved, reset to 0.
16–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 1 The block is selected for erase. 0 The block is not selected.

32.3.11 Address register (C55FMC_ADR)

The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SAD	aH	aM	aL	a256k	a64k	a32k	a16k	ADDR							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ADDR													0		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C55FMC_ADR field descriptions

Field	Description
0 SAD	UTest NVM Address. The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD field is not writable. 0 Address captured is from main array Space. 1 Address captured is from UTest NVM array space.
1 aH	Address High region. The aH bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region. 1 Address captured or to be accessed is from high address region.
2 aM	Address Mid region. The aM bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information.

Table continues on the next page...

C55FMC_ADR field descriptions (continued)

Field	Description
	0 Address captured or to be accessed is not from mid address region. 1 Address captured or to be accessed is from mid address region.
3 aL	Address Low region. The aL bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region. 1 Address captured or to be accessed is from low address region.
4 a256k	Address 256 KB region. The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region. 1 Address captured or to be accessed is from 256 KB region.
5 a64k	Address 64 KB region. The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region. 1 Address captured or to be accessed is from 64 KB region.
6 a32k	Address 32 KB region. The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region. 1 Address captured or to be accessed is from 32 KB region.
7 a16k	Address 16 KB region. The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region. 1 Address captured or to be accessed is from 16 KB region.
8–28 ADDR	Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

32.3.12 UTest 0 register (C55FMC_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	UTE	SBCE	0											CPR	CPA	CPE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

C55FMC_UT0 field descriptions

Field	Description
0 UTE	U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register. 0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked
1 SBCE	Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	0 Single Bit Corrections observation is disabled. 1 Single Bit Correction observation is enabled.
2–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CPR	Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 NAIBP	Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 1 Array Integrity state machine is at a break point. 0 Array Integrity state machine is not currently at a break point.
23 AIBPE	Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 1 Array Integrity breakpoints are enabled during Array Integrity Checks. 0 Array Integrity breakpoints are not enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AISUS	Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	1 Array integrity sequence is suspended. 0 Array integrity sequence not suspended.
26 MRE	Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 Margin reads are enabled. 0 Margin reads are not enabled.
27 MRV	Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 One's margin reads are requested. 0 Zero's margin reads are requested.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AIS	Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. 1 Array integrity sequence is sequential. 0 Array integrity sequence is proprietary sequence.
30 AIE	Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled. 1 Array integrity checks are enabled.
31 AID	Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing. 1 Array integrity check is done.

32.3.13 UMISR register (C55FMC_UM*n*)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MISR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C55FMC_UM*n* field descriptions

Field	Description
0–31 MISR	MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

32.3.14 UMISR register (C55FMC_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

C55FMC_UM9 field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MISR	MISR[288]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained

32.3.15 Over-Program Protection 0 register (C55FMC_OPP0)

The Over-Program Protection 0 (OPP0) register provides a means to protect blocks from being over-programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

- LOWOPP field: The reset value of the LOWOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_OPP0 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWOPP	Low Block Over-Program Protection[13:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Low Blocks starts at LOWOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The LOWOPP register is not writable, and is status only. The default value of the LOWOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.
16–31 MIDOPP	Mid Block Over-Program Protection[15:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Mid Blocks starts at MIDOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted.

Table continues on the next page...

C55FMC_OPP0 field descriptions (continued)

Field	Description
	The MIDOPP register is not writable, and is status only. The default value of the MIDOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

32.3.16 Over-Program Protection 1 register (C55FMC_OPP1)

The Over-Program Protection 1 (OPP1) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 84h offset = 84h

C55FMC_OPP3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 A256KOPP	256K Block Over-Program Protection[47:32]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the 256 KB Blocks starts at 256KOPP[0] and continues until all blocks are accounted. The 256KOPP field is not writable, and is status only. The default value of the A256KOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

32.4 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register (C55FMC_MCR). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

Table 32-1. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- Low Power mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

32.4.1 User Mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

32.4.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read, except when the embedded flash memory is in low power mode. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

> Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] =0) will result in the interlock write being ignored, and address and data will not be updated.

NOTE

> Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See the Module Configuration Register (MCR) section for more information.

32.4.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail (MCR[PEG] = 0), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the MCR[PGM] bit from a 0 to a 1.

   ### NOTE

   Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.
3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

32.4.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

32.4.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

32.4.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

NOTE

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency in not limited, enabling at least 20uS between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

32.4.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

32.4.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset.

32.4.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed.
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored. The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

32.4.1.3.1 Erase software locking

Software Locking affect erase operation. For details on this see Program software locking.

32.4.1.3.2 Erase hardware locking

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

32.4.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

Warning

In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.

Warning

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency is not limited, enabling at least 5mS between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

32.4.2 Low Power mode

In Low Power mode, the embedded flash memory enables VDDF power gating, and disables circuits on the VFLASH domain. No reads from or writes to the embedded flash memory are possible when in Low Power mode.

Prior to entering Low Power Mode, it is required that all program, erase, and UTest operations be stopped prior to entering the mode. If Low Power mode is entered while an operation is suspended, entering Low Power mode will have the same effect as a reset during suspend.

When in Low Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

32.4.3 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

32.4.3.1 Array integrity self check

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks. The data to be read is customer-specific - user code may be programmed into the flash memory and the correct MISR signature is calculated based on that code. Any random or nonrandom code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the system frequency being used. The array integrity check consists of the following sequence of events:

1. Enable UTest mode.

2. Select the block or blocks to be receive the array integrity check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for array integrity check do not need to be unlocked.

   NOTE

   Unselected blocks are still read as part of the array integrity sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

   NOTE

   It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

   NOTE

   For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that AIS be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, ensure that UT0[SBCE] is set.
6. Set the UT0[AIE] bit.
   a. If desired, the array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and then continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers will contain a signature for the portion of the operation that was completed prior to the abort, and will not be deterministic. Prior to doing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.
   b. If desired, the array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the

flash may be done. Once [AID] goes high, UT0[AISUS] may be cleared to resume the array integrity sequence.

NOTE

User mode array reads requested during the array integrity test will be ignored, to ensure that the array integrity operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until the UT0[AID] bit goes high.
8. If breakpoints were enabled, check UT0[NAIBP], and if this is set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear MCR[SBC] or MCR[EER] bits. Then the operation may be resumed by clearing UT0[NAIBP]. Continue to wait until the UT0[AID] bit goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit.

32.4.3.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin reads are done at a read margin level checking for erased bits or programmed bits encroaching on the nominal read level. User margin read is a self-timed event, and is independent of system clocks or wait states selected. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific, and user code may be programmed into the flash memory. Any random or non-random code is valid. Once the operation is completed, the margin read results can be checked by reading the MCR[EER] bit and the MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode.
2. Select the block or blocks to receive margin read check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for margin read do not need to be unlocked.

NOTE

Unselected blocks are still read as part of the margin read sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks will not result in a faster margin read execution time.

NOTE

It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

NOTE

For margin read checks of the flash memory, sequential addressing is recommended. Setting AIS to 0 is possible for Margin Reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. Ensure that the MCR[EER] and MCR[SBC] bits are cleared.
6. If you want to detect single bits during margin read, set UT0[SBCE] to 1.
7. Set the UTO[MRE] bit.
8. Set the UT0[MRV] bit to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Set the UT0[AIE] bit.

NOTE

User mode array reads requested during the margin read test will be ignored, to ensure that the margin read operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

NOTE

During Margin Read operations, with AID low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

10. Wait until the UT0[AID] bit goes high.
    a. If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Array integrity self check for more information.
11. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

12. Write a logic 0 to the UT0[AIE] bit.

32.5 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

Chapter 33
Flash OTP Control

33.1 Introduction

The chapter describes access permissions for flash memory blocks.

33.2 One Time Programmable (OTP) Blocks

The flash memory is divided into several blocks, which can be used as one time programmable (OTP) blocks. If a block is designated to be OTP, it cannot be erased, and already written locations in the flash memory cannot be overwritten (overwrite protection). This applies even if the overwriting would solely clear bits that were still 1.

DCF records control which blocks are set to be OTP. Note that DCF records are applied only during device reset, so appending a record only takes affect after the next reset.

33.3 OTP DCF Records

33.3.1 OTP Record - Low and Mid Blocks

Each flash memory block can be set to be OTP (one time programmable). This record controls the OTP functionality of the low and middle blocks.

0	1	2:15	16:31
rsrvd	*rsrvd*	LOWBLOCKS	MIDBLOCKS

0:31
0100_0010h

Figure 33-1. OTP Record - Low and Mid Blocks

Programming a '1' via a DCF record means the block will be OTP and erase-locked.

33.3.2 OTP Record - High Blocks

Each flash memory block can be set to be OTP (one time programmable). This record controls the OTP functionality of the high blocks.

0:15	16:31
rsrvd	HIGHBLOCK

0:31
0100_0014h

Figure 33-2. OTP Record - High Blocks

The initial value of each OTP control bit is '0'. Programming a '1' via DCF record means the block will be OTP.

33.3.3 OTP Record - Lower 256k Blocks

Each flash memory block can be set to be OTP (one time programmable). This record controls the OTP functionality of the lower 256k blocks.

0:31
256BLCK_L

0:31
0100_0018h

Figure 33-3. OTP Record - Lower 256k Blocks

The initial value of each OTP control bit is '0'. Programming a '1' via DCF record means the block will be OTP.

Chapter 34
Decorated Storage Memory Controller (DSMC)

34.1 Introduction

This section details the hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called "*decorated storage*". It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A "decoration" is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rB,rA` where the data size specifier is defined as 8-bit (`b = `byte), 16-bit (`h = `halfword) or 32-bit (`w = `word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rB,rA` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `"x"` mnemonic suffix, signaling an "indexed" addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in the following figure.

Table 34-1. Power Architecture decorated load and store instruction formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit "decoration". The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

34.2 DSMC block diagram

The following block diagram, Figure 34-1, shows the basic datapaths for the ECC logic in the DSMC. On both the read data path (hrdata) and the write data path (hwdata) there is logic to detect an ECC error and correct the data. The circle with X inside represents an XOR operation. The ecc_hmatrix and ecc_detect blocks are coefficient matrixes based on the Hsiao ECC algorithm. Notice in the recalculation of the s_hwchkbit[7:0] that there is a read chkbit from the slave (hrchkbit), a zero padded result contribution, and a contribution from the hwchkbit from the master. The details of the DSMC bit field and other operations are not shown (represented by the DSMC Operation box).

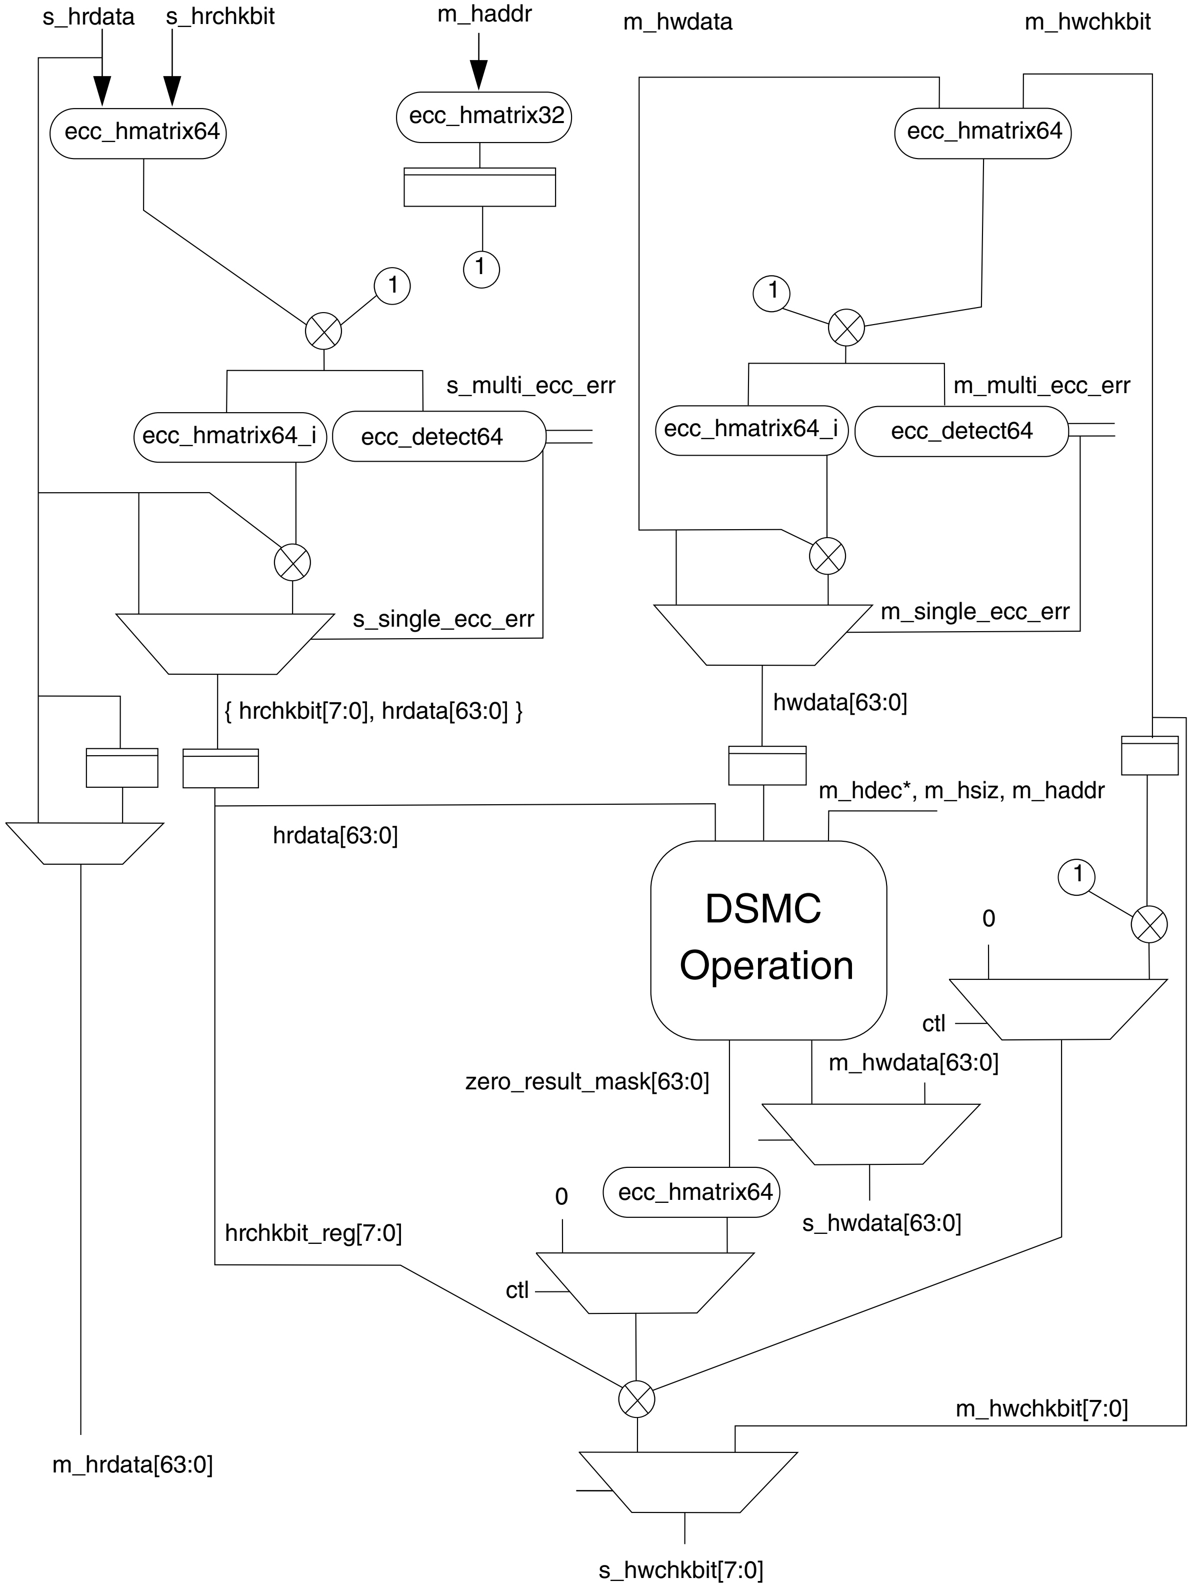

Figure 34-1. DSMC Block diagram

34.3 Decorated stores: `st[b,h,w]d{cb}x rS,rA,rB`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>.<size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

34.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container

Table 34-2. Decoration format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory "container" defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read
if bfw == 0
         then bfw = container

if ((srtbit + bfw) <= container) // generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp  & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp // memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
```

```
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

34.3.1.1 Compare-and-Store (CAST)

Table 34-3. Decoration format: CAST

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CD8							
cast.h	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	CD16															
cast.w	1	0	0	1	CD28																											

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size]  // memory read

if (size == 8)             // define compare_operand
    compare_operand = CD8
else if (size == 16)
          compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand) // compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

34.3.1.1.1 Logical AND (AND)

Table 34-4. Decoration format: AND

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
and. {b,h,w}	1	0	1	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata      // modify
mem[accessAddress, size] = tmp// memory write
```

34.3.1.1.2 Logical OR (OR)

Table 34-5. Decoration format: OR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
or.{b,h,w}	1	1	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata         // modify
mem[accessAddress, size] = tmp// memory write
```

34.3.1.1.3 Logical Exclusive-OR (XOR)

Table 34-6. Decoration format: XOR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
xor.{b,h,w}	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata         // modify
mem[accessAddress, size] = tmp// memory write
```

34.3.1.2 Decorated Loads: `l[b,h,w]d{cb}x rT,rA,rB`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an "extract") operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

34.3.1.2.1 Simple Load (SLD)

Table 34-7. Decoration format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld. {b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

34.3.1.2.2 Registers-and-memory exchange (SWAP)

Table 34-8. Decoration format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
swap.b	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WD8							
swap.h	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	**WD16**															
swap.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)             // store_operand - "modify"
    store_operand = WD8
else if (size == 16)
           store_operand = WD16
    else store_operand = {0x0, WD28} // zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

34.3.1.2.3 Load-and-Set-1(Bit) (LAS1)

Table 34-9. Decoration format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp // rT = rdata = tmp
mask  = 1 << (container - bit - 1) // generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

34.4 DSMC timing diagram

The following timing diagram, shown below, shows a decorated load followed by a decorated store instruction which is then followed by a normal load instruction. Both decorated instructions are read-modify-write instructions and thus they take at least two cycles to execute. In the first cycle an ECC calculation is performed on the read data as well as the write data. Then in the second cycle of the decorated instruction the decorated operation is performed and if it is a decorated store, the result is merged with the read data and sent to the write data bus along with the recalculated ECC write chkbits.

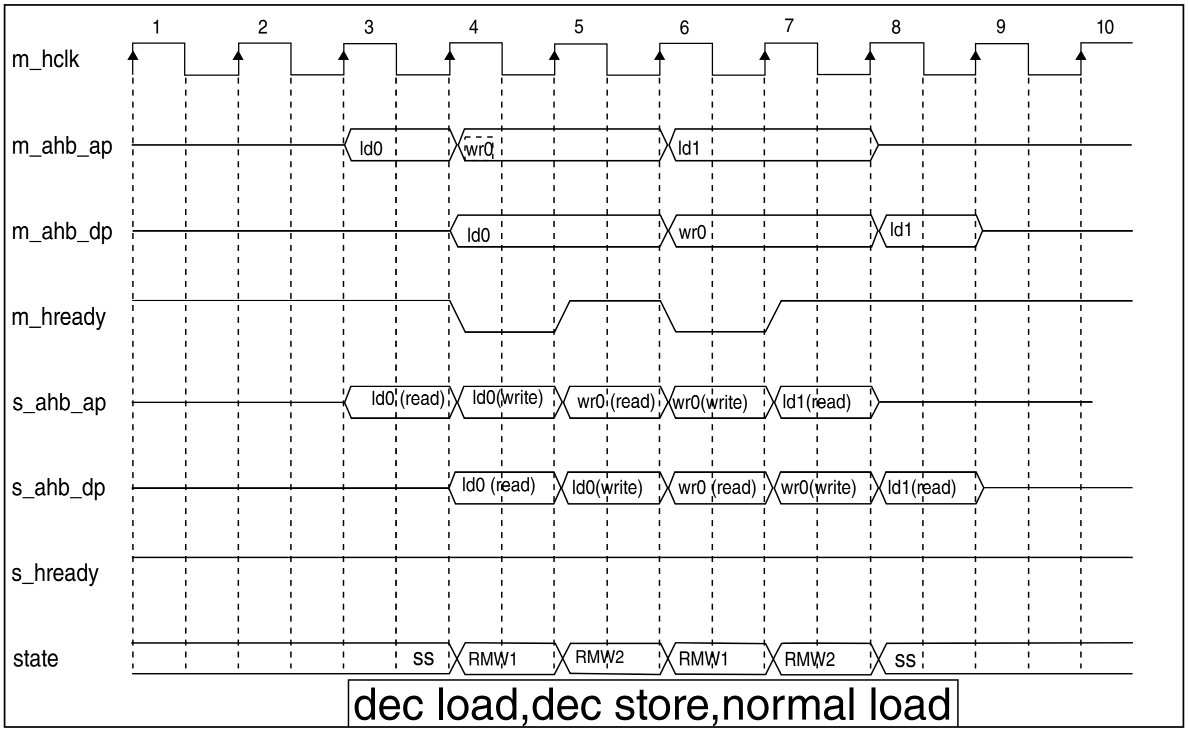

Figure 34-2. DSMC timing diagram

34.5 DSMC instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

Chapter 35
ADC Configuration

35.1 Overview

There are four Analog to Digital Converter (ADC) modules located on the MPC5744P microcontroller. Each ADC consists of 16 channels. The particular ADC set has been chosen with 12-bit Successive Approximation Register (SAR) architecture to allow for precision conversion and sampling in less than 1 µs compounded.

To allow temperature readings while running your application, ADC0 has one channel for temperature sensor TSENS0, and ADC1 has one channel for temperature sensor TSENS1. In addition, all four ADCs have watchdog functionality that compares ADC results against predefined levels before results are stored in the appropriate ADC result location.

The ADCs operate on two different modes: Regular mode and Motor Control mode.

Regular mode features:

- Register based interface with the CPU: one result register per channel
- ADC state machine managing three request flows: regular command, hardware injected command, software injected command
- Selectable priority between software and hardware injected commands
- 16 analog watchdogs comparing ADC results against predefined levels (low, high, range)
- DMA compatible interface

Motor Control mode features:

- Triggered mode only
- Four independent result queues (1x16 entries, 2x8 entries, 1x4 entries)
- Result alignment circuitry (left justified, right justified)
- 32-bit read mode that allows channel ID on one of the 16-bit parts
- DMA compatible interfaces

Integrated with the four ADCs are two Cross Triggering Units (CTUs). Each CTU allows automatic generation of ADC conversion requests on user-selected conditions with minimal CPU intervention. These conversion requests, which occur in what is called CTU Control mode, take place during the PWM period for dynamic configuration.

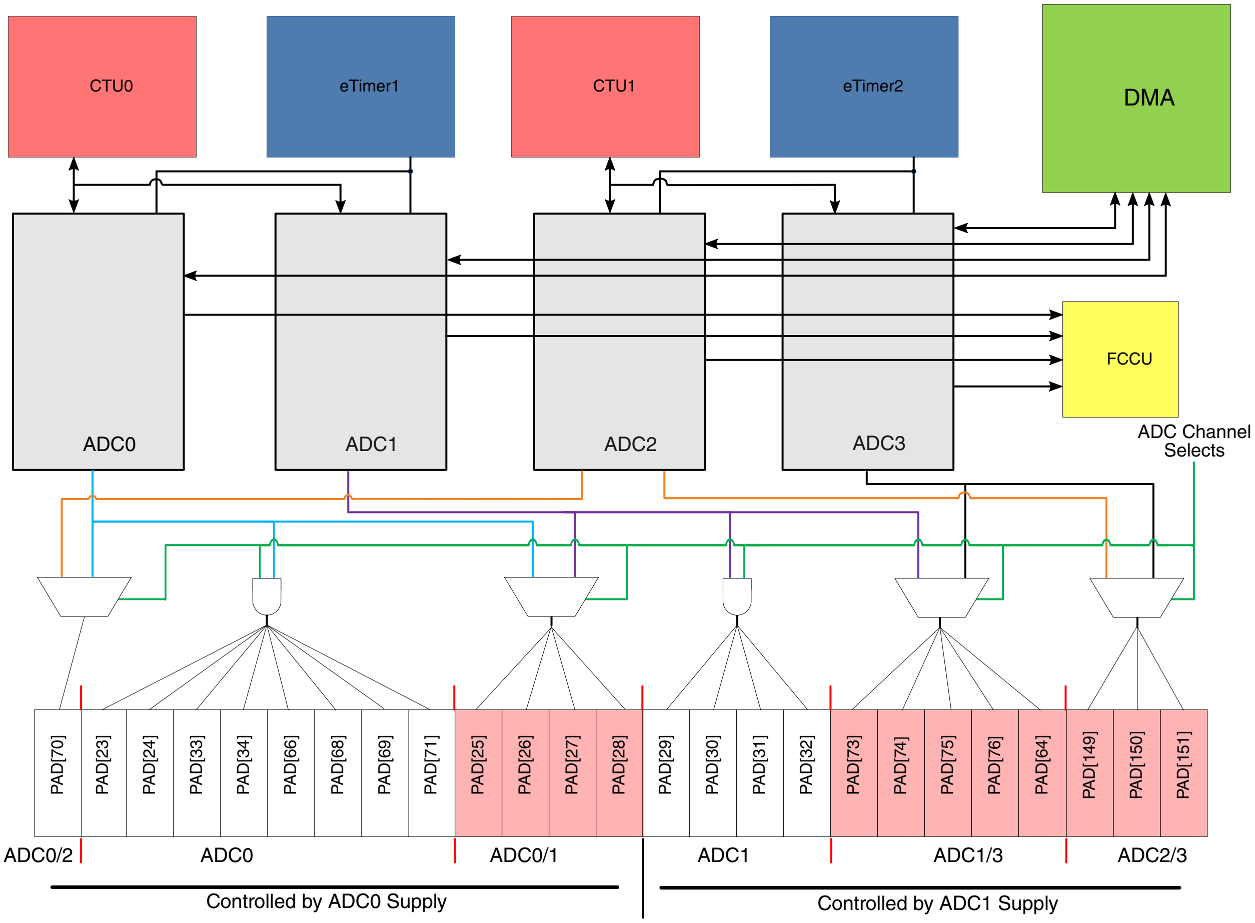
35.2 ADC configuration

35.2.1 Block diagram

The diagram below shows the four different ADCs and their interaction with the other modules on the device. The appropriate pin muxing is also highlighted in the diagram and is described in ADC pin muxing.

NOTE

All four ADCs have only two possible ADC supplies: ADC0 and ADC1. These two supplies must be enabled to use the ADC functionality.



35.2.2 CTU interface

Each ADC is controlled by the CTU (in CTU Control Mode). In this mode, the CTU can control each ADC by sending an ADC command. During the CTU Control Mode, the CPU is able to write in the ADC registers but it can not start a new conversion. For the MPC5744P device the CTU0 is the controller for ADC0 and ADC1 whilst the CTU1 controls the ADC2 and ADC3 modules.

NOTE

CTU Clock (MC_CLK) and ADC_CLK should either be same and synchronous or CTU can also operate with ADC_CLK being an integer plus half (1.5, 2.5,3.5, ...) of MC_CLK clock.

35.2.3 eTimer interface

All four ADCs allow an external trigger source to start a conversion. This feature is enabled through the injection external trigger enable (JTRGEN) bit in the Main Configuration Register (MCR) of the ADC. For the MPC5744P this external trigger feature is connected to timer channel 5 of an eTimer module, through which the eTimer sends an external trigger event. The eTimer1 is connected to ADC0 and ADC1, and the eTimer2 is connected to the ADC2 and ADC3 modules.

35.2.4 DMA interface

For each ADC a DMA request can be performed after the conversion of every channel.

NOTE

For 1N65H, the ADC_DMAE[DCLR] bit is RESERVED and should not be programmed by software.

35.2.5 FCCU interface

Each ADC on the MPC5744P device is connected to the Fault Collection and Control Unit (FCCU) and has the ability to create both critical and non-critical faults. For more on what these faults mean, please refer to the FCCU chapter.

35.3 ADC pin muxing

The following table provides ADC pin multiplexing details.

Table 35-1. ADC pin muxing

ADC		INT/EXT	Signal source		Package Availability
ADC Instance	Channel No		Source	Ext Pin	
Shared external channels - ADC0/1					
ADC0	11	EXT	ADC0_ADC1_AN[11]	PAD[25]	144LQFP 257BGA
ADC1	11

35.3.1 ADC channel conversion

For ADC channel conversion:

- Both Vref VDD_HV_ADRE0 and VDD_HV_ADRE1 must be powered up.
- Both must be at the same level

Chapter 36
Analog-to-Digital Converter (ADC)

36.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

The analog-to-digital converter (ADC) uses Successive Approximation Register (SAR) architecture and provides accurate and fast conversions for a wide range of applications.

36.2 Overview

36.2.1 Parts of the ADC

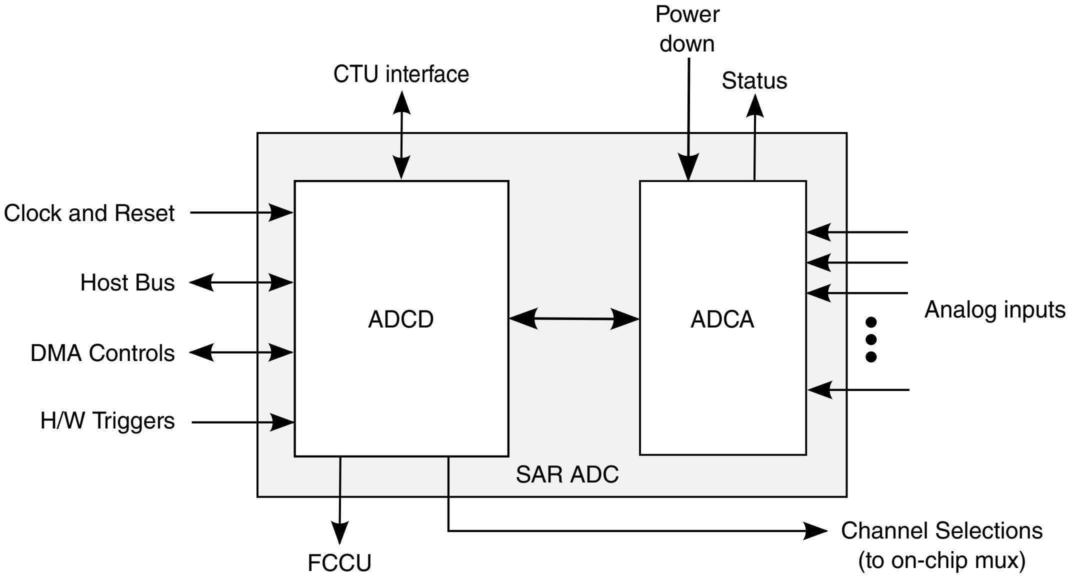

Figure 36-1. ADC high-level block diagram

The ADC is comprised of:

- An ADC digital interface (ADCD). The ADCD holds the configuration, control, and status registers accessible to software via the host bus. The converted value is stored in a register and then transferred through the DMA or host access.
- An ADC analog hard macrocell (ADCA). The analog channel inputs are fed to the inputs of the ADCA. Each channel is sampled for a specific duration and compared with an analog voltage generated with digital code via a digital-to-analog converter (DAC) in the ADCA. The comparison result is given to the ADCD to generate the converted digital value.

36.2.2 ADC clock signals

The ADC uses the following clock signals:

- Bus clock—bus clock at ADCD. Used to access the registers and the operating clock of inter-module interfaces.
- AD_clk—derived from *bus clock*, this signal serves as the operating clock for the ADCA and the SAR controller inside the ADCD.

The relation between the two clocks is determined by the setting of the ADC_MCR[ADCLKSEL] field.

- If ADC_MCR[ADCLKSEL] is 1, the clock signals are the same
- If ADC_MCR[ADCLKSEL] is 0, AD_clk is half of the bus clock.

NOTE

1. Regardless of the setting of the ADC_MCR[ADCLKSEL] field, the maximum clock speed for the ADC clock (AD_clk) is 80 MHz.
2. Depending on your chip's configuration and timing needs, MCR[ADCLKSEL] may always need to be 1.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 1, the ADC clock (AD_clk) is 80 MHz.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 0, the ADC clock (AD_clk) is 40 MHz.

See ADCLKSEL for details on the ADC_MCR register fields.

36.2.3 About ADC channels

36.2.3.1 Channel configuration

ADC channels can be configured in the following ways:

- The sampling duration is controlled independently, through programming the Conversion Timing Register (CTR).
- Separate mask registers can be programmed to configure the channels to be converted (each bit in these registers represents one channel).
- Temperature Sensor (TSENS) and other special channels (band gap, supply etc.) are available on specific channels. (See the chip-specific configuration for availability.)
- Analog watchdogs allow continuous hardware monitoring of the converted value from input channels. (See the chip-specific configuration for availability.)
- Capacitive self test
- Presampling

36.2.3.2 Initiating conversions

Conversions can be initiated by either software or hardware.

The ADCD has an on-chip Cross-Triggering Unit (CTU) interface that can also initiate conversions. The CTU interface supports CTU Control mode.

An example of an application for which CTU triggering is suitable is a current control loop for lamps or LEDs. Using an on-chip timer module as trigger source, a CTU can initiate periodic conversions.

36.2.3.3 Interrupt/DMA support

The ADCD provides interrupt/DMA support for each type of channel for various end-of-channel conversion conditions. Data can be transferred via DMA.

36.2.3.4 Self-test

The ADCD can be configured to periodically check the health of the ADCA through various self-tests and communicate any critical/non-critical faults to an on-chip Fault Collection and Control Unit (FCCU) if available (See the chip-specific section for availability). The severity (critical/noncritical) of the different tests is programmable.

36.3 Features

The following general features are implemented in the ADC. (See the chip-specific section for availability of features, as each instance of an ADC within a chip may support different features.)

- Resolution: 12-bit
- Maximum speed: 1 Mega samples/second at 80 MHz
- 16 channels
- Sampling time register
  - *precision* channels:
    - 0 - 15 (ADC0)
    - 0 - 15 (ADC1)
    - 0 - 4, 10, 14 (ADC2)
    - 0 - 7, 10 - 14 (ADC3)

NOTE

The Temperature Sensor uses the value in the CTR1 register

- Modes of operation:
  - Normal
  - Injected
  - CTU
- Normal mode supports One-Shot/Scan (continuous)
- Injected mode supports One-Shot
- Presampling
- Power-Down mode
- Two abort features that allow you to abort either a single channel in a chain or the full chain in normal and injected mode
- Each channel has a dedicated register for conversion results and mode of operation (normal, injected, or CTU)
- Analog watchdog support:
  - Up to 16 analog watchdogs
  - Configurable for different channels

- Auto clock-off feature
- Programmable clock prescaler (bus clock divided by 2)
- CTU Control mode
- DMA support for each channel
- Interrupts for the following conditions:
  - End of conversion for a single channel for both normal and injected conversions
  - End of conversion for a chain for both normal and injected conversions
  - End of CTU conversion
  - Watchdog thresholds crossover
- Software-initiated calibration
- Self-testing feature

36.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for this module.

NOTE

There will be an Access Error for Reserved and out-of-range addresses. Special exceptions are the Reserved spaces at 039Ch and 03A4h: Do not write or change any value in these locations, or the ADC might malfunction.

NOTE

See the chip-specific configuration information because not all registers are available in all ADC instances.

Control logic registers:

- Main Configuration Register (ADC_MCR)
- Main Status register (ADC_MSR)
- Interrupt Status Register (ADC_ISR)
- Channel Pending register 0 (ADC_CEOCFR0)
- Interrupt Mask Register (ADC_IMR)
- Channel Interrupt Mask Register 0 (ADC_CIMR0)
- Watchdog Threshold Interrupt Status Register (ADC_WTISR)
- Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)
- Analog Watchdog Out of Range Register 0 (ADC_AWORR0)

DMA registers:

- DMA Enable register (ADC_DMAE)
- DMA Channel Select Register 0 (ADC_DMAR0)

Threshold registers:

These registers are used to store the user programmable lower and upper thresholds 12-bit values. These registers include:

- Threshold Register (ADC_THRHLR*n*)

Presampling registers:

- Presampling Control Register (ADC_PSCR)
- Presampling register 0 (ADC_PSR0)

Conversion timing registers:

- Conversion Timing Register 0 (ADC_CTR0)
- Conversion Timing Register 1 (ADC_CTR1)

Mask register: These registers are used to program which input channels must be converted during Normal and Injected conversion. These registers include:

- Normal Conversion Mask Register 0 (ADC_NCMR0)
- Injected Conversion Mask Register 0 (ADC_JCMR0)

Delay registers:

- Power Down Exit Delay Register (ADC_PDEDR)

Data registers:

The conversion results for the internal channels are loaded into data registers. Each data register also gives information regarding the corresponding result. These registers start with CDR0:

- Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Self test registers:

- Self Test Configuration Register 1 (ADC_STCR1)
- Self Test Configuration Register 2 (ADC_STCR2)
- Self Test Configuration Register 3 (ADC_STCR3)
- Self Test Status Register 1 (ADC_STSR1)
- Self Test Status Register 2 (ADC_STSR2)
- Self Test Status Register 3 (ADC_STSR3)
- Self Test Status Register 4 (ADC_STSR4)
- Self Test Baud Rate Register (ADC_STBRR)
- Self Test Analog Watchdog Register 0 (ADC_STAW0R)
- Self Test Analog Watchdog Register 4 (ADC_STAW4R)
- Self Test Analog Watchdog Register 1A (ADC_STAW1AR)
- Self Test Analog Watchdog Register 1B (ADC_STAW1BR)
- Self Test Analog Watchdog Register 2 (ADC_STAW2R)
- Self Test Analog Watchdog Register 5 (ADC_STAW5R)

- Self Test Data Register 1 (ADC_STDR1)
- Self Test Data Register 2 (ADC_STDR2)

Other registers include:

- Calibration, BIST Control and status Register (ADC_CALBISTREG)
- Offset and Gain User Register (ADC_OFSGNUSR)

ADC_MCR field descriptions

Field	Description
0 OWREN	Overwrite enable. 0 Older valid conversion data is not overwritten by newer conversion data. 1 Newer conversion result is always overwritten, irrespective of the validity of older conversion data.
1 WLSIDE	Write Left/Right aligned. 0 The conversion data is written right aligned from (32-resolution) to 31). 1 Data is left aligned (from 16 to (16 + resolution - 1).
2 MODE	One_Shot/Scan.

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
	0 One_Shot Mode: configure the Normal conversion of one chain. 1 Scan Mode: configure continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 TRGEN	External trigger enable. When set, enables the external trigger to start a conversion; if the external trigger feature is needed this bit must be set.
5 EDGE	Start trigger edge detection. If TRGEN is 1 this bit selects the falling (EDGE = zero) or rising (EDGE = one) edge for the external trigger.
6 Reserved	This field is reserved. **NOTE:** User must not overwrite default value of this field.
7 NSTART	Start of Normal conversion. Setting this field starts a normal conversion. In One shot mode: This field is cleared as soon as conversion is started. Setting this field during any ongoing conversion keeps this bit high until the requested conversion is started. **NOTE:** This bit cannot be set (1) when PWDN = 1. This bit is always cleared when PWDN = 1.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 JTRGEN	Injection external trigger enable. When set, enables the external trigger to start a injected conversion; if the external trigger feature is needed for injected conversion then this field must be set.
10 JEDGE	Injection trigger edge selection. Edge selection for external trigger; if JTRGEN is one this bit selects the falling (JEDGE = zero) or rising (JEDGE = one) edge for the external trigger.
11 JSTART	Injection start. Setting this field will start the configured injected conversion chain. Resetting this field has no effect, as the injected chain conversion cannot be interrupted. Setting this field during ongoing Injected conversion keeps this field high value until the requested conversion is started.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CTUEN	Crosstrigger Unit Enable. Enables the crosstriggering unit (CTU). 0 The crosstriggering unit is disabled and the CTU-triggered injected conversion cannot take place. 1 The crosstriggering unit is enabled and the CTUtriggered injected conversion can take place.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 STCL	Self Testing Configuration Lock.

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
	0 No lock 1 The self-testing configuration is locked i.e. STCR1, STCR2, STCR3, STBRR, STAW0R, STAW1AR, STAW1BR, STAW2R, STAW4R, STAW5R are write-protected. It can be used only in CPU and SCAN mode. The lock bit is cleared only by a peripheral reset.
17–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 ADCLKSEL	Analog Clock frequency Selector. This field can be written in Power Down mode only. Please check device specific additional restriction on programming of this field. 0 ADC clock frequency is half of bus clock 1 ADC clock frequency is equal to bus clock
24 ABORT_CHAIN	Abort Chain. If this bit is set the ongoing Chain Conversion is aborted. This bit gets reset by hardware as soon as a new conversion is requested. **NOTE:** Setting this bit in idle state (no normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing CTU conversion this bit also cannot be programmed.
25 ABORT	Abort Conversion. If this bit is set, the ongoing channel conversion is aborted and the next channel conversion is invoked. This bit gets reset by hardware as soon as the new conversion is invoked. This bit cannot be written while self test conversion is ongoing. **NOTE:** Setting this bit in idle state (No Normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing CTU conversion this bit cannot be programmed
26 ACKO	Auto clock off enable. If set, enables the Auto clock off feature.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 REFSEL	Reference voltage selection for ADC analog part. 00 Select VREFH as reference voltage 01 Reserved 10 Reserved 11 Reserved
31 PWDN	Power-down enable. When this bit is set, the analog module is requested to enter Power-Down mode. When the ADC's status is PWDN, resetting this bit will start the ADC's transition to IDLE mode. In CTU control mode MCR[CTUEN] must be reset before entering into power-down mode.

36.4.2 Main Status register (ADC_MSR)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CALIBRTD	0						NSTART	JABORT	0		JSTART	0	SELF_TEST_S	0	CTUSTART
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CHADDR							0			ACKO	0		ADCSTATUS		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

ADC_MSR field descriptions

Field	Description
0 CALIBRTD	This bit indicates the ADC calibration status. This bit gets updated after running the High Accuracy Calibration mode.

Table continues on the next page...

ADC_MSR field descriptions (continued)

Field	Description
	0 Uncalibrated or calibration unsuccessful 1 Calibration was run and it was successful
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 NSTART	This status bit is used to signal that a Normal conversion is ongoing.
8 JABORT	This status bit is used to signal that an Injected conversion has been aborted by CTU. That bit is reset when a new injected conversion starts.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 JSTART	This status bit is used to signal that an Injected conversion is ongoing.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SELF_TEST_S	This status bit signals that self test conversion is ongoing.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CTUSTART	This status bit is used to signal that a CTU conversion is ongoing. This bit is set when a CTU trigger pulse is received and the CTU conversion starts.When Control Mode is enabled this bit is reset when the CTU is disabled (CTUEN set to 0).
16–22 CHADDR	Channel under measure address. Status bits are used to signal which channel is under measure.
23–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 ACKO	Auto clock off enable. This status bit is used to signal if the Auto clock off feature is on.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 ADCSTATUS	Status of the ADC. 000 Idle 001 Power Down 100 Sample 110 Conversion 010 Wait state (waiting to start conversion [external trigger]) 011 Busy in Calibration

36.4.3 Interrupt Status Register (ADC_ISR)

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0											EOCTU	JEOC	JECH	EOC	ECH
W												w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_ISR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 EOCTU	End of CTU conversion. This bit is set for a digital end of conversion on a the CTU Channel; active when set.
28 JEOC	End of injected channel conversion. This bit is set for a digital end of conversion on an injected channel; active when set.
29 JECH	End of injected chain conversion. This bit is set for a digital end of chain conversion on an injected channel; active when set. **NOTE:** If there is no channel selected in the ADC_JCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[JECH] is set and a JECH interrupt is immediately issued (if enabled). Similarly, if no channel is selected in the ADC_NCMR*n* register and a normal conversion is triggered, ADC_ISR[ECH] is set and an ECH interrupt is immediately issued, if enabled.
30 EOC	End of channel conversion. This bit is set for a digital end of conversion on a Normal Channel; active when set.
31 ECH	End of chain conversion. This bit is set for a digital end of chain conversion on a Normal Channel; active when set. **NOTE:** If there is no channel selected in the ADC_NCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

Table continues on the next page...

ADC_ISR field descriptions (continued)

Field	Description
	Similarly, if no channel is selected in the ADC_JCMR*n* register and an injected conversion is triggered, ADC_ISR[JECH] is set and a JECH interrupt is immediately issued, if enabled.

36.4.4 Channel Pending register 0 (ADC_CEOCFR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

ADC_CEOCFR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EOCCH15	EOC Channel 15. When set, the measure of channel 15 is completed.

Table continues on the next page...

ADC_CEOCFR0 field descriptions (continued)

Field	Description
17 EOCCH14	EOC Channel 14. When set, the measure of channel 14 is completed.
18 EOCCH13	EOC Channel 13. When set, the measure of channel 13 is completed.
19 EOCCH12	EOC Channel 12. When set, the measure of channel 12 is completed.
20 EOCCH11	EOC Channel 11. When set, the measure of channel 11 is completed.
21 EOCCH10	EOC Channel 10. When set, the measure of channel 10 is completed.
22 EOCCH9	EOC Channel 9. When set, the measure of channel 9 is completed.
23 EOCCH8	EOC Channel 8. When set, the measure of channel 8 is completed.
24 EOCCH7	EOC Channel 7. When set, the measure of channel 7 is completed.
25 EOCCH6	EOC Channel 6. When set, the measure of channel 6 is completed.
26 EOCCH5	EOC Channel 5. When set, the measure of channel 5 is completed.
27 EOCCH4	EOC Channel 4. When set, the measure of channel 4 is completed.
28 EOCCH3	EOC Channel 3. When set, the measure of channel 3 is completed.
29 EOCCH2	EOC Channel 2. When set, the measure of channel 2 is completed.
30 EOCCH1	EOC Channel 1. When set, the measure of channel 1 is completed.
31 EOCCH0	EOC Channel 0. When set, the measure of channel 0 is completed.

36.4.5 Interrupt Mask Register (ADC_IMR)

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_IMR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved. Reserved
17–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 MSKEOCTU	Mask bit for EOCTU. When set, the interrupt is enabled.
28 MSKJEOC	Mask bit for JEOC. When set, the interrupt is enabled.
29 MSKJECH	Mask bit for JECH. When set, the interrupt is enabled.
30 MSKEOC	Mask bit for EOC. When set, the interrupt is enabled.
31 MSKECH	Mask bit for ECH. When set, the interrupt is enabled.

36.4.6 Channel Interrupt Mask Register 0 (ADC_CIMR0)

The fields in this register globally enable or disable end of conversion interrupts by channels within the range of Channel 0 through 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific details to find which channels are applicable.

Address: 0h base + 24h offset = 24h

ADC_CIMR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CIM15	Channel 15 interrupt enable. When this field is set, the interrupt for channel 15 is enabled.
17 CIM14	Channel 14 interrupt enable. When this field is set, the interrupt for channel 14 is enabled.
18 CIM13	Channel 13 interrupt enable. When this field is set, the interrupt for channel 13 is enabled.
19 CIM12	Channel 12 interrupt enable. When this field is set, the interrupt for channel 12 is enabled.
20 CIM11	Channel 11 interrupt enable. When this field is set, the interrupt for channel 11 is enabled.
21 CIM10	Channel 10 interrupt enable. When this field is set, the interrupt for channel 10 is enabled.
22 CIM9	Channel 9 interrupt enable. When this field is set, the interrupt for channel 9 is enabled.
23 CIM8	Channel 8 interrupt enable. When this field is set, the interrupt for channel 8 is enabled.
24 CIM7	Channel 7 interrupt enable. When this field is set, the interrupt for channel 7 is enabled.

Table continues on the next page...

ADC_CIMR0 field descriptions (continued)

Field	Description
25 CIM6	Channel 6 interrupt enable. When this field is set, the interrupt for channel 6 is enabled.
26 CIM5	Channel 5 interrupt enable. When this field is set, the interrupt for channel 5 is enabled.
27 CIM4	Channel 4 interrupt enable. When this field is set, the interrupt for channel 4 is enabled.
28 CIM3	Channel 3 interrupt enable. When this field is set, the interrupt for channel 3 is enabled.
29 CIM2	Channel 2 interrupt enable. When this field is set, the interrupt for channel 2 is enabled.
30 CIM1	Channel 1 interrupt enable. When this field is set, the interrupt for channel 1 is enabled.
31 CIM0	Channel 0 interrupt enable. When this field is set, the interrupt for channel 0 is enabled.

36.4.7 Watchdog Threshold Interrupt Status Register (ADC_WTISR)

The fields in this register, when set, indicate either the upper or lower threshold value has been crossed for a specific watchdog.

Address: 0h base + 30h offset = 30h

ADC_WTISR field descriptions

Field	Description
0 WDG15H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 15 (WD15). **NOTE:** Write a '1' to this field to clear it.
1 WDG15L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 15 (WD15). **NOTE:** Write a '1' to this field to clear it.
2 WDG14H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 14 (WD14). **NOTE:** Write a '1' to this field to clear it.
3 WDG14L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 14 (WD14). **NOTE:** Write a '1' to this field to clear it.

Table continues on the next page...

ADC_WTISR field descriptions (continued)

Field	Description
4 WDG13H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 13 (WD13). **NOTE:** Write a '1' to this field to clear it.
5 WDG13L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 13 (WD13). **NOTE:** Write a '1' to this field to clear it.
6 WDG12H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 12 (WD12). **NOTE:** Write a '1' to this field to clear it.
7 WDG12L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 12 (WD12). **NOTE:** Write a '1' to this field to clear it.
8 WDG11H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 11 (WD11). **NOTE:** Write a '1' to this field to clear it.
9 WDG11L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 11 (WD11). **NOTE:** Write a '1' to this field to clear it.
10 WDG10H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 10 (WD10). **NOTE:** Write a '1' to this field to clear it.
11 WDG10L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 10 (WD10). **NOTE:** Write a '1' to this field to clear it.
12 WDG9H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 9 (WD9). **NOTE:** Write a '1' to this field to clear it.
13 WDG9L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 9 (WD9). **NOTE:** Write a '1' to this field to clear it.
14 WDG8H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 8 (WD8). **NOTE:** Write a '1' to this field to clear it.
15 WDG8L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 8 (WD8). **NOTE:** Write a '1' to this field to clear it.
16 WDG7H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 7 (WD7). **NOTE:** Write a '1' to this field to clear it.

Table continues on the next page...

ADC_WTISR field descriptions (continued)

Field	Description
17 WDG7L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 7 (WD7). **NOTE:** Write a '1' to this field to clear it.
18 WDG6H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 6 (WD6). **NOTE:** Write a '1' to this field to clear it.
19 WDG6L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 6 (WD6). **NOTE:** Write a '1' to this field to clear it.
20 WDG5H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 5 (WD5). **NOTE:** Write a '1' to this field to clear it.
21 WDG5L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 5 (WD5). **NOTE:** Write a '1' to this field to clear it.
22 WDG4H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 4 (WD4). **NOTE:** Write a '1' to this field to clear it.
23 WDG4L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 4 (WD4). **NOTE:** Write a '1' to this field to clear it.
24 WDG3H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
25 WDG3L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
26 WDG2H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
27 WDG2L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
28 WDG1H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.
29 WDG1L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.

Table continues on the next page...

ADC_WTISR field descriptions (continued)

Field	Description
30 WDG0H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.
31 WDG0L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.

36.4.8 Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)

ADC_WTIMR field descriptions (continued)

Field	Description
5 MSKWDG13L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 13 (WD13) being lower than the programmed lower threshold. When set, the interrupt is enabled.
6 MSKWDG12H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 12 (WD12) being higher than the programmed higher threshold. When set, the interrupt is enabled.
7 MSKWDG12L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 12 (WD12) being lower than the programmed lower threshold. When set, the interrupt is enabled.
8 MSKWDG11H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 11 (WD11) being higher than the programmed higher threshold. When set, the interrupt is enabled.
9 MSKWDG11L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 11 (WD11) being lower than the programmed lower threshold. When set, the interrupt is enabled.
10 MSKWDG10H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 10 (WD10) being higher than the programmed higher threshold. When set, the interrupt is enabled.
11 MSKWDG10L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 10 (WD10) being lower than the programmed lower threshold. When set, the interrupt is enabled.
12 MSKWDG9H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 9 (WD9) being higher than the programmed higher threshold. When set, the interrupt is enabled.
13 MSKWDG9L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 9 (WD9) being lower than the programmed lower threshold. When set, the interrupt is enabled.
14 MSKWDG8H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 8 (WD8) being higher than the programmed higher threshold. When set, the interrupt is enabled.
15 MSKWDG8L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 8 (WD8) being lower than the programmed lower threshold. When set, the interrupt is enabled.
16 MSKWDG7H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 7 (WD7) being higher than the programmed higher threshold. When set, the interrupt is enabled.
17 MSKWDG7L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 7 (WD7) being lower than the programmed lower threshold. When set, the interrupt is enabled.
18 MSKWDG6H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 6 (WD6) being higher than the programmed higher threshold. When set, the interrupt is enabled.
19 MSKWDG6L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 6 (WD6) being lower than the programmed lower threshold. When set, the interrupt is enabled.
20 MSKWDG5H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 5 (WD5) being higher than the programmed higher threshold. When set, the interrupt is enabled.

Table continues on the next page...

ADC_WTIMR field descriptions (continued)

Field	Description
21 MSKWDG5L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 5 (WD5) being lower than the programmed lower threshold. When set, the interrupt is enabled.
22 MSKWDG4H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 4 (WD4) being higher than the programmed higher threshold. When set, the interrupt is enabled.
23 MSKWDG4L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 4 (WD4) being lower than the programmed lower threshold. When set, the interrupt is enabled.
24 MSKWDG3H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being higher than the programmed higher threshold. When set, the interrupt is enabled.
25 MSKWDG3L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being lower than the programmed lower threshold. When set, the interrupt is enabled.
26 MSKWDG2H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being higher than the programmed higher threshold. When set, the interrupt is enabled.
27 MSKWDG2L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being lower than the programmed lower threshold. When set, the interrupt is enabled.
28 MSKWDG1H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being higher than the programmed higher threshold. When set, the interrupt is enabled.
29 MSKWDG1L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being lower than the programmed lower threshold. When set, the interrupt is enabled.
30 MSKWDG0H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being higher than the programmed higher threshold. When set, the interrupt is enabled.
31 MSKWDG0L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being lower than the programmed lower threshold. When set, the interrupt is enabled.

36.4.9 DMA Enable register (ADC_DMAE)

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0														DCLR	DMAEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_DMAE field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DCLR	DMA Clear sequence enable. 0 DMA request cleared by Acknowledge from DMA controller 1 DMA request cleared on read of data registers **NOTE:** When DCLR is set, ADC DMA channels should only execute read accesses on ADC_CDR*n* registers.
31 DMAEN	DMA global enable. When this bit is set, the DMA feature is enabled.

36.4.10 DMA Channel Select Register 0 (ADC_DMAR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_DMAR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DMA15	DMA enable for channel 15. When set, transferring data in DMA mode is enabled for channel 15.
17 DMA14	DMA enable for channel 14. When set, transferring data in DMA mode is enabled for channel 14.
18 DMA13	DMA enable for channel 13. When set, transferring data in DMA mode is enabled for channel 13.
19 DMA12	DMA enable for channel 12. When set, transferring data in DMA mode is enabled for channel 12.
20 DMA11	DMA enable for channel 11. When set, transferring data in DMA mode is enabled for channel 11.
21 DMA10	DMA enable for channel 10. When set, transferring data in DMA mode is enabled for channel 10.
22 DMA9	DMA enable for channel 9.

Table continues on the next page...

ADC_DMAR0 field descriptions (continued)

Field	Description
	When set, transferring data in DMA mode is enabled for channel 9.
23 DMA8	DMA enable for channel 8. When set, transferring data in DMA mode is enabled for channel 8.
24 DMA7	DMA enable for channel 7. When set, transferring data in DMA mode is enabled for channel 7.
25 DMA6	DMA enable for channel 6. When set, transferring data in DMA mode is enabled for channel 6.
26 DMA5	DMA enable for channel 5. When set, transferring data in DMA mode is enabled for channel 5.
27 DMA4	DMA enable for channel 4. When set, transferring data in DMA mode is enabled for channel 4.
28 DMA3	DMA enable for channel 3. When set, transferring data in DMA mode is enabled for channel 3.
29 DMA2	DMA enable for channel 2. When set, transferring data in DMA mode is enabled for channel 2.
30 DMA1	DMA enable for channel 1. When set, transferring data in DMA mode is enabled for channel 1.
31 DMA0	DMA enable for channel 0. When set, transferring data in DMA mode is enabled for channel 0.

36.4.11 Threshold Register (ADC_THRHLR*n*)

Address: 0h base + 60h offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W	▨	▨	▨	▨													▨	▨	▨	▨												
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_THRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for watchdog n.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for watchdog n.

36.4.12 Presampling Control Register (ADC_PSCR)

See the chip configuration details for the availability of this register.

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0									Reserved		Reserved		PREVAL0		PRECONV
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_PSCR field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–26 Reserved	This field is reserved.
27–28 Reserved	This field is reserved.
29–30 PREVAL0	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available four internal voltages for Internal precision channels (Channel 0 to 31). Refer to Presampling channel enable.
31 PRECONV	Convert Presampled value If bit PRECONV is set, presampling is followed by the conversion. Sampling will be bypassed and conversion of presampled data will be done. This bit has no effect on conversion of a channel when presampling on that channel is disabled (for examplei.e PSR*x*[PRES*y*] = 0 , where *x* = register index and *y* = channel number).

36.4.13 Presampling register 0 (ADC_PSR0)

See the chip configuration details for the availability of this register.

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_PSR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 PRES15	Presampling enable for channel 15. When set, presampling is enabled for channel 15.
17 PRES14	Presampling enable for channel 14. When set, presampling is enabled for channel 14.
18 PRES13	Presampling enable for channel 13. When set, presampling is enabled for channel 13.
19 PRES12	Presampling enable for channel 12. When set, presampling is enabled for channel 12.
20 PRES11	Presampling enable for channel 11. When set, presampling is enabled for channel 11.
21 PRES10	Presampling enable for channel 10. When set, presampling is enabled for channel 10.
22 PRES9	Presampling enable for channel 9. When set, presampling is enabled for channel 9.
23 PRES8	Presampling enable for channel 8. When set, presampling is enabled for channel 8.

Table continues on the next page...

ADC_PSR0 field descriptions (continued)

Field	Description
24 PRES7	Presampling enable for channel 7. When set, presampling is enabled for channel 7.
25 PRES6	Presampling enable for channel 6. When set, presampling is enabled for channel 6.
26 PRES5	Presampling enable for channel 5. When set, presampling is enabled for channel 5.
27 PRES4	Presampling enable for channel 4. When set, presampling is enabled for channel 4.
28 PRES3	Presampling enable for channel 3. When set, presampling is enabled for channel 3.
29 PRES2	Presampling enable for channel 2. When set, presampling is enabled for channel 2.
30 PRES1	Presampling enable for channel 1. When set, presampling is enabled for channel 1.
31 PRES0	Presampling enable for channel 0. When set, presampling is enabled for channel 0.

36.4.14 Conversion Timing Register 0 (ADC_CTR0)

Conversion timing register. CTR0 is associated with channels 0 to 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0

ADC_CTR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–19 Reserved	This field is reserved.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 Reserved	This field is reserved.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles. **NOTE:** The Bandgap voltage sampling time is controlled by CTR0[INPSAMP]. CTR0[INPSAMP] is also used for the external channel sample time. When the user software needs to sample the Bandgap voltage, it must change the CTR0[INPSAMP] value to allow for a longer time while the Bandgap is being sampled, then change its value back to the normal value for sampling external channels.

36.4.15 Conversion Timing Register 1 (ADC_CTR1)

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_NCMR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CH15	Normal sampling enable for channel 15. When set, normal sampling is enabled for channel 15.
17 CH14	Normal sampling enable for channel 14. When set, normal sampling is enabled for channel 14.
18 CH13	Normal sampling enable for channel 13. When set, normal sampling is enabled for channel 13.

Table continues on the next page...

ADC_NCMR0 field descriptions (continued)

Field	Description
19 CH12	Normal sampling enable for channel 12. When set, normal sampling is enabled for channel 12.
20 CH11	Normal sampling enable for channel 11. When set, normal sampling is enabled for channel 11.
21 CH10	Normal sampling enable for channel 10. When set, normal sampling is enabled for channel 10.
22 CH9	Normal sampling enable for channel 9. When set, normal sampling is enabled for channel 9.
23 CH8	Normal sampling enable for channel 8. When set, normal sampling is enabled for channel 8.
24 CH7	Normal sampling enable for channel 7. When set, normal sampling is enabled for channel 7.
25 CH6	Normal sampling enable for channel 6. When set, normal sampling is enabled for channel 6.
26 CH5	Normal sampling enable for channel 5. When set, normal sampling is enabled for channel 5.
27 CH4	Normal sampling enable for channel 4. When set, normal sampling is enabled for channel 4.
28 CH3	Normal sampling enable for channel 3. When set, normal sampling is enabled for channel 3.
29 CH2	Normal sampling enable for channel 2. When set, normal sampling is enabled for channel 2.
30 CH1	Normal sampling enable for channel 1. When set, normal sampling is enabled for channel 1.
31 CH0	Normal sampling enable for channel 0. When set, normal sampling is enabled for channel 0.

36.4.17 Injected Conversion Mask Register 0 (ADC_JCMR0)

Enable bits of Injected Sampling for channel 0 to 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + B4h offset = B4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ADC_PDEDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PDED	The delay between the power down bit reset and the start of conversion. The power down delay is calculated as (PDED x 1/[ADC_clock_frequency]).

36.4.19 Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 100h offset + (4d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												VALID	OVERW	RESULT	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CDATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_CDR*n* field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.

Table continues on the next page...

ADC_CDR*n* field descriptions (continued)

Field	Description
13 OVERW	Overwrite data Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the OWREN bit of MCR register.
14–15 RESULT	These two bits reflect the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–31 CDATA	Converted Data 11:0. **Note:** It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

36.4.20 Threshold Register (ADC_THRHLR*n*)

Address: 0h base + 280h offset + (4d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_THRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for channel x.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for channel x.

36.4.21 Channel Watchdog Select Register 0 (ADC_CWSELR0)

WSEL_CHn[3:0] bit field: Selects the threshold register which provides the values to be used for upper and lower thresholds for channel n.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 2B0h offset = 2B0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_STCR2 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MSKWDSERR	Interrupt enable (STSR1[WDSERR] status bit) 0 Interrupt disabled 1 Enables the STSR1[WDSERR] status bit to generate an interrupt indication.
5 SERR	Error fault injection bit (write only). Writing 1 to this bit sets the STSR1[ERRx] status bits once only. Reading always returns 0. Setting this bit does not affect any of the self test data registers.
6 MSKWDTERR	Interrupt enable (STSR[WDTERR] status bit) 0 Interrupt disabled 1 Enables the STSR1[WDTERR] status bit to generate an interrupt indication.

Table continues on the next page...

ADC_STCR2 field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MSKST_EOC	Interrupt Enable bit for STSR2[ST_EOC] 0 Interrupt disabled 1 Enables the STSR1[ST_EOC] status bit to generate an interrupt indication. (IMR[MSKEOC] must also be enabled.)
9–12 Reserved	This field is reserved.
13 MSKWDG_EOA_C	Interrupt enable (WDG_EOA_C status bit) 0 Interrupt disabled 1 Enables the STSR1[WDG_EOA_C] status bit to generate an interrupt indication.
14 Reserved	This field is reserved.
15 MSKWDG_EOA_S	Interrupt enable (WDG_EOA_S status bit) 0 Interrupt disabled 1 Enables the STSR1[WDG_EOA_S] status bit to generate an interrupt indication.
16 MSKERR_C	Interrupt enable (ERR_C status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_C] status bit to generate an interrupt indication.
17 Reserved	This field is reserved.
18 MSKERR_S2	Interrupt enable (ERR_S2 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S2] status bit to generate an interrupt indication.
19 MSKERR_S1	Interrupt enable (ERR_S1 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S1] status bit to generate an interrupt indication.
20 MSKERR_S0	Interrupt enable (ERR_S0 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S0] status bit to generate an interrupt indication.
21–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 EN	Self testing channel enable. The TEST conversions are enabled. Enables the TEST channel only in CPU mode. This bit should be set before starting the normal conversion and should not be changed while conversion is ongoing. This bit should be reset only after end of conversion for the last self test channel has been received. 0 Disabled 1 Enabled
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADC_STCR2 field descriptions (continued)

Field	Description
27 FMA_WDSERR	Fault mapping for the Watchdog Sequence error. By default a failure on the watchdog sequence is mapped on the NCF fault line. 0 NCF mapping 1 CF mapping
28 FMA_WDTERR	Fault mapping for the Watchdog Timer error. By default a failure on the watchdog sequence is mapped on the NCF fault line. 0 NCF mapping 1 CF mapping
29 FMA_C	Fault mapping for self test algorithm C. By default a failure on the self test C algorithm is mapped on the CF fault line. 0 NCF mapping 1 CF mapping
30 Reserved	This field is reserved.
31 FMA_S	Fault mapping for the self test algorithm BGAP. By default a failure on the Supply algorithm is mapped on the CF fault line. 0 NCF mapping 1 CF mapping

36.4.27 Self Test Configuration Register 3 (ADC_STCR3)

This register defines ADC self testing capabilities in CPU mode or CTU mode.

Address: 0h base + 348h offset = 348h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_STCR3 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 ALG	Algorithm scheduling. ONE-SHOT mode algorithm scheduling:

Table continues on the next page...

ADC_STCR3 field descriptions (continued)

Field	Description
	• 00: Algorithm S (single step=MSTEP) • 01: Reserved • 10: Algorithm C (single step=MSTEP) • 11: Algorithm S (default) For test/debug purposes. SCAN mode algorithm scheduling: • 00: Algorithm S • 01: Reserved • 10: Algorithm C • 11: Algorithm S + Algorithm C (default) The baud rate for the execution of the selected algorithm is defined by the STBRR register.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 MSTEP	One shot mode: Current step for Algorithm S or Algorithm C. • MSTEP = 0 to (NUM_SUPPLY_STEPS-1) for algorithm S • MSTEP = 0 to (NUM_C_STEPS-1) for algorithm C Scan mode: This field is not used in scan mode as always single step execution (interleaved mode) is performed. It should be programmed to zero in scan mode. **NOTE:** All unused valued are RESERVED and should not be used.

36.4.28 Self Test Baud Rate Register (ADC_STBRR)

Used to set the baud rate for the selected baud rate in SCAN mode as well as the watchdog timer value.

Address: 0h base + 34Ch offset = 34Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0													WDT			0								BR							
W

ADC_STBRR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 WDT	The watchdog timer value is used to monitor that the algorithm sequence is correctly executed within the safe time period. The self testing watchdog is enabled setting the STAWxR[WDTE] control bits. Default value is 10 ms. A fixed pre-scaler runs on the ADCdig clock (80 MHz). (Prescalar value is fixed at 1024). 000 0.1 ms ((0008h * Prescalar) cycles at 80 MHz) 001 0.5 ms ((0027h * Prescalar) cycles at 80 MHz)

Table continues on the next page...

ADC_STBRR field descriptions (continued)

Field	Description
	010 1 ms ((004Eh * Prescalar) cycles at 80 MHz) 011 2 ms ((009Ch * Prescalar) cycles at 80 MHz) 100 5 ms ((0187h * Prescalar) cycles at 80 MHz) 101 10 ms ((030Dh * Prescalar) cycles at 80 MHz) 110 20 ms ((061Ah * Prescalar) cycles at 80 MHz) 111 50 ms ((0F42h * Prescalar) cycles at 80 MHz)
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BR	Baud rate for the selected algorithm in SCAN mode (MCR[MODE] = 1). 00h Max scheduling rate (NOMINAL rate) ... FFh Min scheduling rate (NOMINAL rate scaled by 255) This field should be programmed when ST_EN is zero i.e. before enabling self test channel.

36.4.29 Self Test Status Register 1 (ADC_STSR1)

Address: 0h base + 350h offset = 350h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0				WDSERR	0	WDTERR	OVERWR	ST_EOC	0				WDG_EOA_C	0	WDG_EOA_S

W	w1c		w1c	w1c	w1c											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_STSR1 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WDSERR	Watchdog sequence error of the ADC sub-system (check for algorithm step sequence). The WDSERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDSERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDSERR] mapping. **NOTE:** This bit is set only if STAWxR[WDTE] = ‘1’. 0 No failure 1 Failure occurred
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADC_STSR1 field descriptions (continued)

Field	Description
6 WDTERR	Watchdog timer error of the ADC sub-system (algorithm check for completion within safe time). The WDTERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDTERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDTERR] mapping. 0 No failure 1 Failure occurred
7 OVERWR	Overwrite error. Used to notify when the STSR1[ERRx] bit is overwritten by a newer one. The OVERWR status bit is cleared writing 1. A 0 write is an invariant operation. The new error status is written or discarded according to the MCR[OWREN] bit value. To avoid OVERWR indication, the ERRx status bit must be cleared (via software).
8 ST_EOC	Self Test EOC Bit. This bit is set along with EOC bit when end_of_conversion signal is received from ADC analog for self test channel. The ST_EOC status bit is cleared by writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled by STCR2[MSKST_EOC]. (Also, IMR[MSKEOC] has to be enabled.)
9–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 WDG_EOA_C	This bit indicates that Algorithm C has been completed. This bit is generated after the last STEP of algorithm C is executed. The WDG_EOA_C status bit is cleared by writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_C] = 1). This bit is set only if STAW4R[WDTE] = 1. For CTU conversions, this bit is significant only for Burst mode of operation.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 WDG_EOA_S	This bit indicates that Algorithm S has been completed. This bit is generated after the last STEP of algorithm S is executed. The WDG_EOA_S status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_S] = 1). This bit is set only if STAW0R[WDTE] = ‘1’. For CTU conversions, this bit is significant only for Burst mode of operation.
16 ERR_C	Indicates an error on the self testing channel (algorithm C). The ERR_C status bit is cleared writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_C] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_C bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical type or Non-Critical type lines are asserted according to the STCR2[FMAx] mapping. 0 No C-algorithm ERROR 1 C-algorithm ERROR occurred
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ERR_S2	Indicates an error on the self testing channel (algorithm SUPPLY, step2). The ERR_S2 status bit is cleared by writing a 1b. A 0b write is an invariant operation. It generates an interrupt (“ipi_int_er” line) if enabled (STCR2[MSKERR_S2] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S2 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping. 0 No ERROR occurred on the sampled signal 1 ERROR occurred on the sampled signal

Table continues on the next page...

ADC_STSR1 field descriptions (continued)

Field	Description
19 ERR_S1	Indicates an error on the self testing channel (algorithm SUPPLY, step1). The ERR_S1 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S1] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S1 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping. 0 No VDD ERROR 1 VDD ERROR occurred
20 ERR_S0	Indicates an error on the self testing channel (algorithm SUPPLY, step0). The ERR_S0 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S0] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S0 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical type fault lines are asserted according to the STCR2[FMAx] mapping. 0 No VREF ERROR 1 VREF ERROR occurred
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–26 STEP_C	Step of the algorithm C when an ERR_C has occurred. 0.. (NUM_C_STEPS-1) => algorithm C
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

36.4.30 Self Test Status Register 2 (ADC_STSR2)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 354h offset = 354h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OVFL	0			DATA1

36.4.33 Self Test Data Register 1 (ADC_STDR1)

The ADC_STDR1 register contains the most current result data for conversions executed during ADC self test. Additionally, the register contains status bits to indicate whether result data has been read and whether existing conversion data has been overwritten by a newer result.

NOTE

1. For Algorithm S step 1, the result data contained in this register is not the final step 1 result. The step 1 data is the conversion of the analog supply (VDDA). This VDDA conversion result is divided by the Algorithm S step 0 conversion data and the result is written to the ADC_STDR2 register.
2. The least significant 3 bits of the analog supply (VDDA) conversion executed during Algorithm S step 1 processing are always '0'. The conversion performed in Algorithm S Step 1 is not on the full scale analog supply. Instead, the voltage sampled is VDDA / 8. The prescaling is done to avoid issues that can arise in the analog portion of the ADC when VREFH = VDDA = 3.3 V, or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 before being written to this register to scale the result to the expected level, which results in the 3 least significant bits having a value of '0'.

Address: 0h base + 370h offset = 370h

ADC_STAW0R field descriptions

Field	Description
0 AWDE	Analog watchdog enable (related to the algorithm S (step 0)) Enables/disables the comparison of the conversion result from the ADC's supply self test step 0 to the thresholds contained in this register (THRH and THRL) 0 Disabled 1 Enabled
1 WDTE	Watchdog timer enable (related to the algorithm S) Enables/disables the watchdog timer monitoring function for all ADC supply self test steps. The watchdog timer verifies: • Correct sequence of the algorithm (step sequence) • Execution of the algorithm within the safe time period as defined by STBRR[WDT] As soon as the watchdog timer is enabled the algorithm execution must be detected within the safe time period. The watchdog timer is reset each time the algorithm restarts. This bit should be set only in scan mode.

Table continues on the next page...

ADC_STAW0R field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for Algorithm S step 0 If the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA]) > THRH. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for Algorithm S step 0 If the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA]) < THRL. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

36.4.36 Self Test Analog Watchdog Register 1A (ADC_STAW1AR)

This register contains values associated with the ADC's supply self test step 1, in which the analog supply (VDDA) is sampled and a fixed point division is performed, dividing the conversion result by the result from step 0 (bandgap voltage). The integer portion of the result is handled separately from the fractional part, i.e., they have separate data registers and threshold fields. Thresholds in this register are applied to the integer portion of the result. Thresholds in the ADC_STAW1BR register are applied to the fractional portion of the result.

ADC_STAW2R field descriptions

Field	Description
0 AWDE	Analog watchdog enable related to the algorithm S (step2).
1–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for channel x (unsigned coding). If the analog watchdog is enabled, the STSR1[ERR_S2] status bit is set if STDR1[TCDATA] < THRL. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

36.4.39 Self Test Analog Watchdog Register 4 (ADC_STAW4R)

This register contains ADC self test configuration controls associated with the ADC's capacitive self test (also referred to as "Algorithm C") sequence, which samples voltages from the ADC's internal capacitor matrix. The watchdog enable fields (AWDE and WDTE) affect all Algorithm C steps; the threshold fields (THRH and THRL) fields are specific to Algorithm C Step 0.

4–15 THRH	High threshold value for step 0 of C algorithm.

Table continues on the next page...

ADC_STAW4R field descriptions (continued)

Field	Description
	This value is read by the ADC as twos-complement, but should be written positive. If the watchdog is enabled (STAW4R[AWDE] = 1) and STDR1[TCDATA] > STAW4R[THRH], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for step 0 of C algorithm. This value is read by the ADC as twos-complement, and it should be the negative of STAW4R[THRH]. If the watchdog is enabled (STAW4R[AWDE] = 1) and STDR1[TCDATA] < STAW4R[THRL], then STSR1[ERR_C] is set. **NOTE:** The settings in this register are applicable only to step 0 of the ADC's capacitive self test. Refer to the ADC_STAW5R register for settings applicable to other capacitive self test steps. The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

36.4.40 Self Test Analog Watchdog Register 5 (ADC_STAW5R)

This register contains ADC self test threshold values associated with all capacitive self test (also referred to as "Algorithm C") steps other than Step 0, which is controlled by fields in the ADC_STAW4R register.

Note that the threshold values in this register are distinctly different than those in the ADC_STAW4R register. The threshold values in this register do not represent a voltage conversion value relative to the ADC high reference voltage, but instead represent the upper and lower thresholds for the absolute difference between the voltage sampled and converted in an Algorithm C step and the voltage sampled and converted in Algorithm C Step 0. Ideally, the difference will be zero.

Address: 0h base + 398h offset = 398h

24–31 OFFSET_USER	Offset User (2's complement format)

36.5 Functional description

The following sections detail the ADCD interfaces as well as the functionality of this module.

36.5.1 Conversion

After power-up or reset, the ADC is in power-down mode until the MCR[PWDN] field is written. There are some configurations, listed below, available only in power-down mode, that must be handled before exiting power down.

- Clock selection for SAR Controller (AD_clk): MCR [ADCLKSEL]

After the above configurations, ADC need to be taken out from power-down mode by writing '0' into MCR [PWDN], Conversions can be initiated now in the following modes:

- Normal
- Injected
- CTU Triggered

36.5.1.1 Normal conversion

The conversion mode generally used to convert channels is called normal conversion. Programming the available Normal Conversion Mask Register(s) (ADC_NCMR*n*) selects the channel(s). Each channel can be individually enabled by setting a bit in the corresponding field of the NCMR*n* register.

- NCMR0 serves *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)
  - 0 - 4, 10, 14 (ADC2)
  - 0 - 7, 10 - 14 (ADC3)

The mask register(s) must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends. Conversion always starts from the lowest channel number selected and sequentially goes to the highest number.

36.5.1.1.1 Starting a normal conversion

After programming the MCR and NCMR0*n* register(s), a normal conversion is started via *software* by setting the MCR[NSTART] bit.

To start a normal conversion via *external trigger*, enable external trigger by setting the (MCR[TRGEN] bit. A programmed event (rising/falling edge depending on MCR[EDGE] bit) on the normal trigger input starts the conversion.

Detection of an active edge defined by MCR[EDGE] bit (rising=1, falling=0) on the external trigger will start the normal conversion.

36.5.1.2 Normal conversion operating modes

Two operating modes are available for normal conversion:

- One-Shot mode
- Scan mode

The MCR[MODE] bit determines which mode is used during a normal conversion. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, during which the sampled analog value is converted to digital as shown in the figure below.

Figure 36-2. Normal conversion flow

36.5.1.2.1 One shot mode

In one shot mode (MCR[MODE] = 0) a sequential conversion specified in the following mask register(s) is performed only once:

- NCMR0

At the end of each conversion, the digital result of the conversion is stored into the corresponding data register(CDRx, x = channel number).

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in One-Shot mode. Conversion starts with channel B, followed by the conversion of channels D and E. At the end of conversion of channel E, the scanning of channels will stop.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time, MCR[NSTART]is reset by hardware, allowing the software to program a new start of conversion in advance. In this case, the newly requested conversion starts after completing the running/current conversion. However, for the sake of simplicity and straightforwardness, it is advisable to program the NSTART bit for the new conversion only after the completion of the running conversion. To know the end of conversion of running chain, application will either wait for an End of Chain (ECH) Interrupt or check the status of MSR[NSTART] prior to setting MCR[NSTART] again.

If the conversion chain is started by the external trigger, the trigger input will not be observed by the ADC block until the current conversion chain is finished. After the chain is over, the next chain can be invoked/triggered by another hardware trigger edge.

36.5.1.2.2 Scan mode

In scan mode (MCR[MODE] = 1), a sequential conversion of *n* channels specified in the NCMR*n* register(s) is continuously performed. At the end of each conversion, the converted result is stored into the corresponding data registers, as in One-Shot mode.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One-Shot mode, the MCR[NSTART] bit is not reset automatically in Scan mode. It can be reset by software when you need to stop Scan mode. In that case, the ADC completes the current chain and, after the last conversion, resets MSR[NSTART].

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in Scan mode. MCR[MODE] = 1 is set for Scan mode. Conversion starts from channel B, followed by the conversion of channels D and E. At the end of the conversion of channel E, the conversion of channel B starts again, followed by the conversion of channels D and E. This sequence repeats itself until MCR[NSTART] is reset by software.

This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished.

NOTE

If the conversion is started by an external trigger, MCR[NSTART] is not set. As a consequence, once started, the only way to stop a Scan mode conversion started by an external trigger is to set the MCR[MODE] bit to 0.

36.5.1.2.3 End of conversion

In both modes, at the end of each conversion an end-of-conversion (EOC) interrupt is issued if enabled by the corresponding mask bit in the following register(s):

- CIMR0

Additionally, the EOC interrupt must enabled in the IMR register. After the conversion of all the channels selected in the NCMR*n* register(s) is completed and the conversion operation is considered finished, ISR[ECH] is set and an end-of-chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]). The corresponding channel bit within the appropriate CEOCFR*n* register is updated to indicate that data is available on the data register (CDR*n*) of the respective channel. If there is no channel selected in the NCMR*n* register(s) and there is a start of conversion trigger, then ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

NOTE

To add or remove channels to/from the ongoing chain:

1. Clear the MCR[NSTART] bit
2. Set/clear mask bit for the needed channels in NCMR*n*
3. Set the MCR[NSTART] bit

36.5.1.3 Injected conversion

An injected conversion is a conversion chain that can be injected at any time, including into an ongoing normal conversion chain. To do so, configure the injected mask register(s):

- JCMR0

As in a normal conversion, each internal or external channel can be individually selected for injected conversion.

- JCMR0 controls *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)
  - 0 - 4, 10, 14 (ADC2)
  - 0 - 7, 10 - 14 (ADC3)

Injected conversion can only be run in One-Shot mode, and can only interrupt a normal conversion. Please note, that a CTU conversion cannot be interrupted by an injected conversion. In this case, the injected conversion is discarded. When an injected chain is inserted into an ongoing normal chain, the ongoing normal channel is suspended and the injected channel request is processed. After completing the last channel in the injected chain, normal conversion resumes from the channel at which it was suspended as shown in the following figure.

normal conversion resumes from the last aborted channel

Figure 36-3. Injected sample/conversion sequence

36.5.1.3.1 Starting injected conversion

The injected conversion can be started via *software* by setting the MCR[JSTART] bit to start an injected conversion; the current normal conversion is suspended and the injected chain is converted.

To start an injected conversion via *external trigger*, enable external triggering by setting MCR[JTRGEN]=1. A programmed event (rising/falling edge depending on MCR[JEDGE] bit) on the injection trigger input starts the injected conversion.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time, the MCR[JSTART] bit is reset, allowing software to program a new start of conversion in advance. In that case, the new requested conversion starts after the running conversion is completed.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit in IMR) and at the end of the chain an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit in IMR). The status bit ISR[JECH] is also set.

If the content of all the injected conversion mask registers (JCMRn) is zero (i.e., no channel is selected) the interrupt JECH is immediately issued to resume normal operation or conversion mode.

The corresponding channel bit in the appropriate CEOCFR*n* register is updated to indicate that data is available in the data register (CDR) of the respective channel.

Once started, injected chain conversion cannot be interrupted by Normal or another Injected conversion. A CTU trigger has the higher priority; injected conversion has a lower priority. Therefore, only a CTU trigger can interrupt an ongoing injected conversion. In this case, the injected conversion will be discarded.

36.5.1.4 Aborting conversions

Two different abort functions are provided:

- A single channel abort
- A chain abort

You can abort the ongoing conversion by setting the MCR[ABORT] bit. The current conversion is aborted and the conversion of the next channel of the chain is immediately started. The abort action may take 1 to 4 cycles of the bus clock to abort the current conversion depending on the state of the conversion. At the start of any conversion and at the end of a particular conversion, when internal state counters are changing, then abort is delayed by a maximum of 3 cycles to take all states in stable condition. Abort also should not be programmed along with and within 3 cycles of programming the MCR[NSTART] or MCR[JSTART]. This may not have a significant impact from software point of view since on any SoC the next write access comes only after a minimum of 3 clock cycles.

NOTE

Programming Abort or Abort chain with NSTART or JSTART in idle condition has no effect.

For a Normal conversion chain having only one channel:

1. Abort re-runs the conversion again from the Abort point

If both Normal and Injected conversions are started by hardware trigger and they are coming in a particular cycle-dependent manner, e.g.,

1. When Abort is programmed one cycle after start of Injected conversion followed by a start of normal conversion in the next cycle of Abort, or
2. When Abort comes one cycle after the start of a normal conversion followed by the start of an Injected conversion in next cycle,

then Abort may or may not be detected and the Missing of Abort will consume maximum of 1 μs (one conversion time) more time for the execution of to-be-aborted conversion.

In the case of an abort operation, the MSR[NSTART/JSTART] bit remains set, if not in last channel of chain, and the MCR[ABORT] bit is reset as soon as the channel is aborted. The EOC corresponding to the aborted channel is not generated. This behavior is true for Normal or Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is also possible to abort the current chain of conversions by setting the MCR[ABORTCHAIN] bit. In that case, the behavior of the ADC depends on the MCR[MODE] bit (One-Shot/Scan) for Normal conversion. In One-Shot mode, MSR[NSTART] is automatically reset together with the MCR[ABORTCHAIN]. Otherwise, in Scan mode, a new chain is started, and the current chain is aborted. The EOC of the current aborted conversion is not generated, but an ECH interrupt is generated to signal the end of the chain. For Injected conversion, the behavior of ABORTCHAIN is same as for One-shot Normal conversion. In this case, MSR[JSTART] is automatically reset together with the MCR[ABORTCHAIN].

When an ABORTCHAIN is requested while an injected chain is running over a suspended normal chain, both injected and normal chains are aborted; both MSR[NSTART] and MSR[JSTART] are reset. ABORT and ABORTCHAIN requests are ignored during CTU conversion. ABORT requests are also discarded during Self-Test conversion.

36.5.2 Crosstriggering Unit interface

The Crosstriggering Unit (CTU) interface enhances the injected conversion capability of the ADC. The CTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. The CTU/ADC interface is shown in the figure below. The CTU generates a trigger and a channel number to be converted. A single channel is converted for each request. After performing the conversion, the ADC returns the result.

The conversion result is also saved in the corresponding data register and it is compared with watchdog thresholds if requested.DMA and interrupt feature of ADC can also be used during CTU conversion.

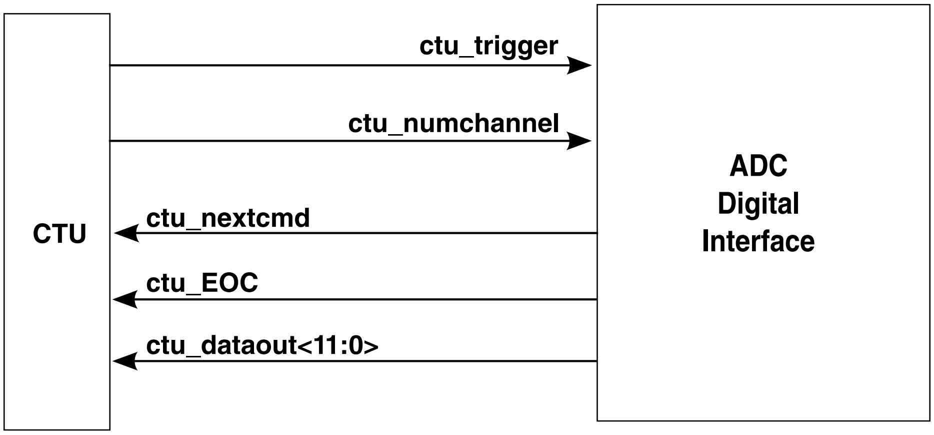

Figure 36-4. ADC Crosstriggering Unit

The CTU interface has one mode of operation, Control.

The CTU interface is enabled by programming the MCR[CTUEN] bit.

36.5.2.1 CTU Control mode

In CTU Control mode, if enabled via MCR[CTUEN], the CPU is able to write in the ADC registers, but it cannot start a conversion. Conversion requests can be generated only by a CTU trigger. If a normal or injected conversion is requested when the CTU is enabled (MCR[CTUEN]), it will be automatically discarded.

Along with CTU trigger the ctu_numchannel is taken as channel and CTU conversion starts. MSR[CTUSTART]is set automatically at this point and it remains set unless the CTU is disabled by resetting MCR[CTUEN].

CTU conversions must be requested when calibration is over. If a CTU trigger is received during calibration, the calibration stops immediately in order to satisfy the CTU request. Calibration will fail in this case.

If another CTU trigger is received before the ctu_nextcmd signal, the new request is discarded.

36.5.3 ADC clock prescaler and sample time settings

The clock (AD_clk) provided to the ADC's SAR controller, which controls the ADCA, must satisfy particular conditions of frequency and duty cycle. The maximum acceptable frequency is 80 MHz with a duty cycle equal to 50% (±5%).

The AD_clk frequency can be scaled by programming the MCR[ADCLKSEL] bit. If this bit is set, AD_clk frequency is the same as the bus clock. Otherwise, AD_clk frequency is half of the bus clock. MCR[ADCLKSEL] can only be written in power-down, when MCR[PWDN] = 1.

Sampling times are controlled by settings in the Conversion Timing Register (CTR*n*).

- CTR0 controls sampling time for *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)
  - 0 - 4, 10, 14 (ADC2)
  - 0 - 7, 10 - 14 (ADC3)

The exception is the Temperature Sensor channel, which always uses the CTR1 value. See Conversion Timing Register 1 (ADC_CTR1) for details.

36.5.4 Presampling

Presampling allows the ADC internal capacitor to precharge or discharge to a defined level before it starts the actual sampling/conversion of the analog input coming from the pads. This is useful for resetting information (history effect/offset) regarding the last converted data. During presampling, the ADC samples the internally generated voltage while, during sampling, the ADC samples the analog input coming from the pads.

Presampling can be enabled/disabled on an individual channel by setting the corresponding bit in the applicable PSR*n* register.

- PSR0 controls precision channels

After enabling the presampling for a channel, the normal sequence of operation is presampling + sampling + evaluation for that channel. Sampling of the channel can be bypassed by setting PSCR[PRECONV]. When sampling of a channel is bypassed, the presampled voltage will be converted.

See Conversion time for the conversion's timing equation.

in the PSCR Register. For Channel C and D Total Conversion Clock cycles = (P)+ (C)

Figure 36-6. Presampling sequence with PRECONV = 1

36.5.4.1 Presampling channel enable

The presampling channels are selected by programming the presampling register (Presampling Control Register (ADC_PSCR)). These are used to enable analog switches that samples an internally generated voltage. It is possible to select presample voltage from four internally available voltages depending on the value of PREVAL*x* [*x* = 0,1,2] fields in the PSCR register as given in Table 36-1.

Table 36-1. Presample voltage selection

PREVAL*n*	Presampling voltage
00b	Presample voltage 1: VSS_HV_ADV (High voltage ground for ADC)
01b	Presample voltage 2: VDD_HV_ADV/8 (Power High voltage Supply for ADC, SGEN divided by 8)
10b	Presample voltage 3: VSS_HV_ADRE1 (High voltage ground for ADC/TSENS)
11b	Presample voltage 4: VDD_HV_ADRE1 (High voltage reference for ADC/TSENS)

The PREVALn fields are associated with specific channels, as shown in Table 36-2.

Table 36-2. PREVAL*n* channel association

Field	Channels
PREVAL0	• 0 - 15 (ADC0) • 0 - 15 (ADC1) • 0 - 4, 10, 14 (ADC2) • 0 - 7, 10 - 14 (ADC3)

The temperature sensor channel is an exception. It can be mapped with any of the channels, but it uses the PREVAL1 value to select the presample voltage because its physical properties may be different than the other internal precision channels.

36.5.5 Programmable analog watchdog

NOTE

> The number of analog watchdogs and channels may vary depending on the ADC instance on your chip. Please see the chip-specific section for how many are available on each instance.

The analog watchdogs are used for determining whether the result of a conversion lies within a given guard area (as shown in Figure 36-7) specified by an upper and a lower threshold value named THRH and THRL, respectively.

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside the guard area, then the corresponding threshold violation interrupt is generated.

The comparison result is stored as WTISR[WDGxH] and WTISR[WDGxL], as explained in the following table. Depending on the WTIMR[MSKWDGxL] and WTIMR[MSKWDGxH] mask bits, an interrupt is generated upon threshold violation.

Table 36-3. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

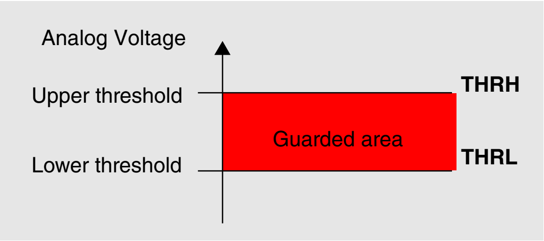

Figure 36-7. Guarded Area

36.5.5.1 Analog watchdog setting

For each watchdog there is one Threshold value (Low and High) Register (THRHLR).

The analog watchdog for each channel can be enabled independently by programming CWENR*n* register bits.

- CWENR0 controls *precision* channels:
    - 0 - 15 (ADC0)
    - 0 - 15 (ADC1)
    - 0 - 4, 10, 14 (ADC2)
    - 0 - 7, 10 - 14 (ADC3)

The availability of these registers depends on device configuration.

Threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLRx,(x=0..15)) by the WSEL_CHx field of CWSELRx (x=0..11) register.

Each CWSELRx register holds selection for 8 consecutive channels. CWSELR0 holds 8 WSEL_CH fields for channel 0 to 7. Likewise CWSELR1 is for channel 8 to 15 and so on. The availability of fields and registers depends on device configuration.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in the Analog Watchdog Out of Range Register (AWORR).

For example, if channel number 12 is to be monitored with the threshold values in register THRHLR3, then CWSELR1[WSEL_CH4] needs to be programmed with 3. The enabling will be done by setting the bit corresponding to channel 12 in the CWENR0 register.

A set of threshold values (THRHLRx) can be linked to several ADC channels. The threshold values to be selected for a channel needs be programmed only once in the CWSELRx register.

36.5.6 DMA functionality

A Direct Memory Access (DMA) request can be programmed after the conversion of every channel by setting the respective masking bit in the following register(s):

- DMAR0

The DMA masking registers must be programmed before starting any conversion.

The DMA transfers can be enabled using the ADC_DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

36.5.7 Interrupts

ADC generates the following maskable interrupt signals:

- End-of-conversion interrupt (EOC) request
- End-of-chain interrupt (ECH) request
- End-of-injected conversion interrupt (JEOC) request
- End-of-injected chain interrupt (JECH) request
- End-of-CTU conversion interrupt (EOCTU) request
- Watchdog threshold interrupt (WDGxL and WDGxH) requests

Interrupts are generated during the conversion process to signal events, like the end of a conversion, as explained in the register description for the Interrupt Status Register (ISR). The ISR and the Interrupt Mask Register (IMR) allow you to check and enable the interrupt request.

Interrupts can be individually enabled on a channel-by-channel basis by programming the Channel Interrupt Mask Register (CIMR).

A Channel Pending Register (CEOCFR*n*) is also provided in order to signal which of the channels' measurement has been completed.

Analog Watchdog interrupts are enabled by Watchdog Threshold Interrupt Mask Register (WTIMR) and the status can be checked at Watchdog Threshold Interrupt Status Register (WTISR). The watchdog interrupt source sets two fields, WDGxH and WDGxL, for each channel monitored in the WTISR.

In particular, the EOC, ECH, EOCTU, JEOC, and JECH interrupt lines are combined (OR-ed) on the same line. The EOC interrupt request is cleared by clearing either ISR[EOC] or all bits of CEOCFR. The JEOC interrupt request is cleared by clearing either ISR[JEOC] or all bits of CEOCFR. The EOCTU interrupt request is cleared by clearing either ISR[EOCTU] or all bits of CEOCFR. Also, the self-test end of algorithm interrupts STSR1[WDG_EOA_S] and STSR1[WDG_EOA_C] are combined.

All WDGxH and WDGxL requests are combined on the second line.

Another interrupt on the third line is a combination of WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, and ERR_C in STSR1.

The ISR register contains the interrupt pending request status. If you want to clear a particular interrupt event status, then writing a 1 to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all the other bits of the ISR register must be programmed to 0.)

36.5.8 Power-Down mode

The analog part of the ADC can be put in Power-Down mode by setting the MCR[PWDN] bit, which shuts off the ADCA and stops the clock in the SAR controller. After power-on or device reset, the ADCA is kept in Power-Down mode by default, so this state must be exited before starting any operation by resetting the MCR[PWDN] bit. In Power-Down mode, no conversion and calibration can be started. Trigger from CTU during power down is discarded. In the ADC power-down mode, the CTU must not start any conversion.

The MCR[PWDN] bit may be programmed high at any time. However, if a conversion is ongoing, then the ADCA cannot be sent immediately into Power-down mode. In fact, the ADC enters Power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN function.

The ADC status in MSR[ADCSTATUS] field shows Power-down status only when ADC enters in Power-down mode.

If CTU is enabled and MSR[CTUSTART] is 1, then the MCR[PWDN] bit cannot be set. When CTU Control mode enabled, the application needs to reset the CTUEN bit before entering Power-Down mode.

After the power-down phase is complete, the process ongoing before the power-down phase must be restarted manually .

NOTE

Resetting the MCR[PWDN] bit and setting the MCR[NSTART] or MCR[JSTART] bit during the same cycle is forbidden.

36.5.9 Auto-Clock-Off mode

To reduce power consumption in Idle mode (without going into Power-Down mode), an auto-clock-off feature can be enabled by setting MCR[ACKO]. When enabled, the analog clock is automatically switched off when no operation is ongoing (that is, when no conversion has been programmed).

NOTE

This feature must remain off during calibration.

36.5.10 Calibration and Self Test

The ADC is calibrated and tested runtime through the same set of test conversions. The test result is used for computation and stored during the calibration process and only checked in self test. The two modes of running tests are as follows:

1. High-Accuracy mode/Calibration. Needs to be run after power-on reset and whenever required in runtime operation. Calibrates the ADC and updates calibration-related registers.
2. Quick-Check mode/Self-Test. Used for runtime functional self-tests to improve reliability. Catches any runtime fault or accuracy shift from previously calibrated values. Please see the chip-specific configuration information as self-test may not be available in all ADC instances.

The following sections describe both and the steps for executing them.

36.5.10.1 Calibration (High Accuracy mode)

The functioning of the analog block of ADC depends on the accuracy of values of its various parts and parameters, such as the value of capacitors, the gain of the amplifier, and so on. Due to variations in manufacturing and various runtime environmental effects, the actual values may differ from the ideal values for which the ADC is targeted.

Because of these deviations, the ADC's converted values contain errors. To eliminate these errors, the ADC must be calibrated prior to any conversion.

In the calibration process, a fixed known reference voltage (VrefH) is sampled many times and converted under various controlled conditions to check for deviations between these converted values and predefined values.

The deviations, known as offsets or modified values, are used to eliminate errors during the data processing of normal conversions.

Calibration needs to be performed after every power-up/destructive reset and whenever required in runtime operation. The applicability of destructive reset depends on device configuration. Please check the ADC configuration for the device.

Note

> The ADC must be recalibrated if the operating conditions (particularly VrefH) change significantly. Calibration should also be performed again if the Self-Test indicates that a recalibration is needed.

Recommended settings:

- Clock frequency = 40 MHz
- Averging – Maximum (512)

The calibration process will take ~12ms of time with the above recommended settings.

NOTE

> If the ADC clock frequency is > 40MHz during calibration, the accuracy of the calibration process will be compromised, hence the performance of the ADC. Thus, it is strongly recommended to run the calibration with 40 MHz clock.

As calibration is a time consuming process, it can be performed after a long interval – probably several hours of operation – but it is not necessary to recalibrate frequently. The goal is to maximize the possible accuracy delivered from conversion and to catch any structural fault to flag the error.

The calibration routine sets the fail flag (CALBISTREG[TEST_FAIL]) to indicate:

- A fault in ADC
- A premature abort of the calibration

Calibration is aborted if a normal conversion is initiated during calibration; this is called *premature termination*. The terminating conversion and the immediate next one to it will have invalid result in this case.

CALBISTREG[TEST_FAIL] = 1 indicates that the ADC health is not good and that it will not meet specifications.

To execute this routine, follow these steps:

1. Configure the ADC to 40 MHz.
    - Put the ADC in power down mode: set MCR[PWDN]
    - Configure clock divider selection: reset MCR[ADCLKSEL]
    - Power-up the ADC: reset MCR[PWDN]
2. Configure the Calibration, BIST Control, and Status Register (CALBISTREG). The default values are set for maximum accuracy (recommended).
3. Start calibration: set CALBISTREG[TEST_EN].

4. Wait for calibration to complete. Check MSR[ADCSTATUS] or till CALBISTREG[C_T_BUSY] becomes 0.
5. Check the value of MSR[CALIBRTD] to determine whether calibration was successful.
6. If MSR[CALIBRTD] = 1, calibration was successful; otherwise, it failed, and CALBISTREG[TEST_FAIL] = 1.
7. If required, reconfigure the ADC clock frequency for normal operation.

36.5.10.2 Self test (Quick-Check/Safety mode)

For devices used for very critical applications requiring high reliability it is important to check at regular intervals if the ADC is functioning correctly. For this purpose, Self Testing feature (Quick Check) has been incorporated inside ADC.

The following testing algorithms are available for checking:

- Supply Self test: algorithm S. It includes the conversion of the bandgap, supply and VREF voltages. It includes a sequence of three test conversions (steps). The supply test conversions must be an atomic operation (no functional conversions interleaved).
- Capacitive Self test: algorithm C. It includes a sequence of 12 test conversions (steps) to check the capacitive array.

The capacitive test of ADC requires only 12 steps to test itself.

The capacitive array is used as DA converter to generate from V_{REFH} 12 different voltages by distributing and partially discharging portions of the capacity array. These 12 voltages are sampled using some redundant capacities. C algorithm may be compared to providing 12 different voltages to ADC and validate the conversion result.

Two kinds of tests are performed in this mode, as shown in the following table.

Table 36-4. Quick-Check mode tests

STCR3 [ALG]	STCR3 [MSTEP]	Description	Outcome	Comment
00 supply test	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	—
	1	Supply self-test (analog supply)	Measures the analog supply voltage (VDDA) and divides the result by the bandgap voltage (result from Algorithm S step 0). The VDDA conversion result is written to ADC_STDR1[TCDATA]. The final result (after division) consists of an integer portion and a fractional portion, both of which	The least significant 3 bits of the analog supply (VDDA) conversion executed during Algorithm S step 1 processing and written to ADC_STDR1[TCDATA]) are always '0'. The conversion performed in Algorithm S Step 1 is not the full scale analog supply. Instead, the voltage sampled is VDDA / 8. The prescaling is done

Table continues on the next page...

Table 36-4. Quick-Check mode tests (continued)

STCR3 [ALG]	STCR3 [MSTEP]	Description	Outcome	Comment
			are written to the ADC_STDR2 register.	to avoid issues that can arise in the analog portion of the ADC when VREFH = VDDA = 3.3 V, or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 within the digital part of the ADC to scale the result to the expected level, which results in the 3 least significant bits having a value of '0'.
	2	Supply self-test (reference voltage high)	Measures the high reference voltage of the ADC	—
01	Reserved	—	—	—
10 capacitive test	0–11	One of the ADC-BIST steps is being run	The difference or error of individual value from the previously calibrated value is being returned (unsigned) as an ADC result that is compared with a programmed value in the analog watchdog register(s) to detect any fault. The difference or error may be caused by any runtime fault, runtime accuracy shift, or device noise.	Ideally, the result value is expected to be 0. If the returned value is higher, this indicates runtime fault or accuracy shift. This indicates that ADC should be recalibrated in High-Accuracy mode to check whether the reported error can be handled by recalibrating or whether permanent damage to ADC has occurred.
11	Supply test followed by Capacitive test in same sequence as shown above	—	—	—

This mode is described in the following sections.

36.5.10.2.1 Self test initialization and application information

ADC samples the internal V_{REFH} for the C algorithm and samples different supplies (bandgap, V_{DD} and V_{REFH}) for the supply algorithm. It also provides signals for the following:

- Scheduling self-testing algorithms using configuration registers
- Monitoring the converted data using analog watchdog registers
- Flagging the error to FCCU in case a failure occurs in any of the algorithms

ADC mode	TEST channel (ADCdig)	TEST channel (CTU)
CPU mode (MCR[CTUEN] = 0)	Yes	No

Table continues on the next page...

ADC mode	TEST channel (ADCdig)	TEST channel (CTU)
	• One-Shot mode • Scan mode	
CTU Control mode	No	Yes

36.5.10.2.2 CPU mode

In this case, the test channel works similarly to a normal conversion. The test channel is enabled by setting STCR2[EN].

Self-test conversions are executed by interleaving the Normal conversions. The sequencing of steps of the selected algorithm for test channel depends on the operating mode of normal conversion, selected by MCR[MODE].

In One-Shot mode, if the test channel is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in the STCR3 register. So, in One-Shot mode, the sequence is as follows:

1. Program NCMR*n* register(s) to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (for 1 MSPS operation)
3. Program MCR[MODE] = 0 to select One-Shot mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMPx].
5. Select the self-testing algorithm in STCR3[ALG]. The default is algorithm S.
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of allnormal conversions, the step number programmed in STCR3[MSTEP] of the self-testing algorithm selected by STCR3[ALG] is executed similar to a normal functional channel.
10. On receiving an end-of-conversion for the test channel, the digital result is written in STDR1[TCDATA] andSTDR1[VALID] is set. Also, ISR[EOC], ISR[ECH], and STSR1[ST_EOC] are set. See the register descriptions (Self Test Data Register 1 (ADC_STDR1), Interrupt Status Register (ADC_ISR), and Self Test Status Register 1 (ADC_STSR1)) for details of settings for each test.
11. The state machine returns to the Idle state.

For example: in a device with channels A-B-C-D-E-F-G-H, channels B-D-E are to be converted in One-Shot mode. MODE = 0 is set for One-Shot mode. Refer to Conversion. Conversion for channels B-D-E are done. After channel E test channel conversion is done and ISR[ECH] and ISR[EOC] are set.

MSR[NSTART] is automatically set when the normal conversion starts; it is reset at the end of conversion for the test channel.

In Scan mode, the consecutive steps of the selected self test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed at once without any functional conversion interleaved). So, in Scan mode the sequence is as follows:

1. Program the NCMR*n* registers to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (for 1 MSPS operation)
3. Program MCR[MODE] = 1 to select Scan mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMPx].
5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected (that is, all algorithms are executed step-by-step one after the other).
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of chain forthe normal conversions (assuming a default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] is set.
10. At the end of conversion of test channel for the last step of algorithm S, the digital result is written in STDR1[TCDATA] and STDR1[VALID] is set. At the same time, MSR[SELF_TEST_S] is reset. For step 1, the integral part and fractional part are written in STDR2[IDATA] and STDR2[FDATA]. Also, ISR[EOC], ISR[ECH], and STSR2[ST_EOC] are set.
11. The next normal conversion chain starts.
12. At the end of the normal conversion chain, Step0 of the C algorithm is executed.
13. At the end of conversion of test channel for Step0 of the C algorithm, the digital result is stored in STDR1[TCDATA] and STDR1[VALID] is set (if MCR[OVERWR] is set). Also, ISR[EOC], ISR[ECH], andSTSR2[ST_EOC] are set.
14. The next normal conversion chain starts.
15. At the end of the normal conversion chain, step1 of C algorithm is executed.
16. This process continues for all steps of all algorithms.
17. The state machine returns to the Idle state when MCR[NSTART] is written to 0.

NOTE

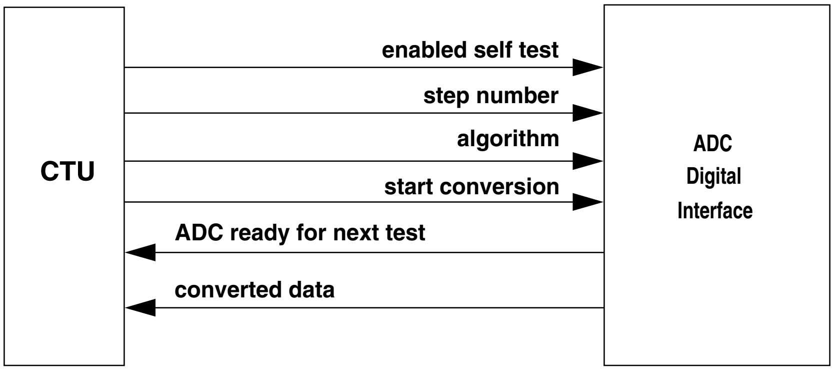
- Instead of starting a normal conversion with software (by setting MCR[NSTART]), if it is started by external trigger, the test channel behavior remains the same.

- Test channel conversion is not performed during injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, injection conversion arrives, then the test channel is aborted (just as a normal functional channel) and injected conversions are done. After injected conversions are completed, the test channel resumes from the step at which it was aborted. In this case, MSR.SELF_TEST_S remains high during the injected conversion.
- For self testing, MCR[MODE]should be programmed at least one cycle *before* setting MCR[NSTART]. It should not be changed thereafter until a conversion is ongoing.

36.5.10.2.3 CTU mode

For this chip, the operating mode is CTU Control mode.

When MCR[CTUEN] is set, the test channel conversion can be started only by the CTU interface; software cannot start it. STCR2[EN] does not have any effect in CTU mode. The CTUEN bit should not be changed while normal conversion is ongoing. The interface between the CTU and ADCD (for self test) is shown here:



For self testing conversions in CTU mode, the CTU asserts an indication that enables self test along with the CTU trigger that starts the self test conversion. The algorithm and the step number to be executed is put on the interface respectively.

NOTE

As already mentioned for algorithm S, the three steps must be atomic. In CTU mode, this is managed by the CTU itself; that is, the CTU has to send three triggers (one for each step) asserting the indication that enables self test and updating the step number for each step.

36.5.10.2.4 Abort and Abort Chain for self-test channel

Setting MCR[ABORT] during self-test channel has no effect.

In One-Shot mode, if MCR[ABORTCHAIN] is set when the test channel conversion is ongoing, the test channel is aborted and ECH is set. In this case, EOC for the test channel is not generated.

In Scan mode, if MCR[ABORTCHAIN] is set when test channel STEP N is ongoing, then the test channel STEP N is aborted and the next chain conversion starts. At the end of this chain, STEP N conversion is performed again. (If algorithm S is ongoing, the full algorithm is executed again.)

36.5.10.2.5 Self-test analog watchdog

ADCD also provides a monitor for the values returned by the ADC analog macro for self-test algorithms. The analog watchdogs are used to determine whether the result of conversion for self-test algorithms lie in a particular guard area. For this purpose, separate Self-Test Analog Watchdog Registers are provided for each algorithm.

If the analog watchdog feature is enabled (STAWxR[AWDE] = 1), a comparison is performed between the converted value and the threshold values after the conversion of each step of an algorithm. If the converted value does not lie between the upper and lower threshold values specified by the Analog Watchdog Register of the particular algorithm, the corresponding error bit (STSR1[ERR_x]) is set and the step number during which the error occurred is updated in STSR1[STEP_x] (in case of the C algorithm) and erroneous data is written in STSR4[DATAx]. STSR1[ERR_x] generates an interrupt if enabled by the corresponding mask bit in STCR2. The fault indication is also given to the FCCU via the Critical and Non-Critical fault lines, so that necessary action can be taken at chip level.

The analog watchdog feature works differently in the case of algorithm S. As already mentioned, algorithm S is always an atomic operation. So, separate error bits are provided in STSR1 for each step of algorithm S to avoid an overwrite in case an error occurs in more than one step. Hence, there are separate mask bits for each step in STCR1. For the same reason, separate fields in the status registers (STSR2 and STSR3) exist to store erroneous data for each step.

In step 0 of supply algorithm, ADC measures the band gap voltage (+1.2V), which is assumed to be stable with very little variation (up to +/- 1.5%). The converted data of step 0 is measured with high (THRH) and low (THRL) threshold defined in STAW0R if enabled (STAW0R[AWDE]). The STSR1[ERR_S0] is set to '1' if threshold is violated; once set, it is cleared to '0' by writing '1' to it.

In step 1 of supply algorithm, ADC measures the Analog supply (Vdda) for the ADC, and then a fixed point division is performed with the result of step 1 (ADC supply voltage) and step 0 (band gap voltage). It takes around 26 cycles after EOC for step 1 to get a divided value, and it is the divided value on which analog watchdog checks are applied. So, the value to be compared for step 1 contains the integer as well as fractional part; two registers (STAW1AR and STAW1BR) are provided for this. The comparison is done first for the integer part using the threshold values programmed in STAW1AR. If the integer part lies in the range, the fractional part comparison is skipped; otherwise, it is compared with the values programmed in STAW1BR. The following table summarizes this feature for step 1.

Table 36-5. Algorithm S (step 1) threshold comparison

STDR2[IDATA] (integer part)	STDR2[FDATA] (fractional part)	STSR1[ERR_S1]
> STAW1AR[THRH]	Any value	Set
< STAW1AR[THRL]	Any value	Set
== STAW1AR[THRH]	> STAW1BR.THRH	Set
== STAW1AR[THRL]	< STAW1BR.THRL	Set

In step 2 of supply algorithm, ADC measures the High Reference voltage (Vrh); (VREF/VREF) is measured in order to check the integrity of sampling signal. For this particular conversion, no higher threshold value is required as the ideal value is 0xFFF. Only the lower threshold value is programmed in STAW2R.

In the supply self-test algorithm, the band gap is measured with regard to the reference voltage (Vrh) in step 0. The result is capable of catching mismatches between them. Step 1 measures the supply with regard to reference (Vrh), and the result is taken to do a ratio (Vdda/Vbg). If the band gap voltage remains within +/-1.25% of its ideal value of 1.2 V, then by setting appropriate values of THRH and THRL in watchdog registers, the ADC self-test can catch more than 4% variation in supply and reference faithfully.

Algorithm C has total 12 steps. Output data of step 0 is compared with the threshold values stored in STAW4R, if enabled in the same register. The result of step 0 is used as an offset for rest of the steps (step 1 to 11). The absolute difference between the converted data of each of the steps (1 to 11) with the data of step 0 are compared with the threshold values of STAW5R, if enabled in STAW4R. Error in any step is indicated by STSR1[ERR_C] and the data in error case is captured in STSR4.

Calculation of Threshold values:

S1 Algorithm: Calculated voltage comparison method:

The user software can implement a method of calculating S1 algorithm IDATA, FDATA, the THRH values, and the THRL values to voltages and then perform a comparison of the calculated voltage to the calculated THRH voltage and calculated THRL voltage.

The steps involved in this method are as follows:

1. Calculate the high threshold voltage:

   (STAW1AR [THRH] + (STAW1BR [THRH] / 4096)) * Vbandgap
2. Calculate the low threshold voltage:

   (STAW1AR [THRL] + (STAW1BR [THRL] / 4096)) * Vbandgap
3. Calculate the converted results to voltage:

   (STDR2 [IDATA] + (STDR2 [FDATA] / 4096)) * Vbandgap
4. Compare result from step 3 to THRH and THRL.S1 algorithm passes

   If (low threshold voltage <= converted voltage <= high threshold voltage).

36.5.10.2.6 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm implemented and checks that the algorithm completes within a safe time period. Watchdog timers can be enabled for CPU as well as CTU conversions. Each algorithm has a different watchdog timer that runs independently of the other. The watchdog timer for a particular algorithm can be enabled by setting STAWxR[WDTE]. The safe time value can be programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point at which step 0 of the same algorithm starts again.

The sequence is as follows:

1. Program NCMR0 to select channels to be converted for normal conversion in Scan mode (MODE = 1).
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (14 h) (for 1 MSPS operation)

3. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected; that is, all algorithms will be executed step-by-step, one after the other.
4. Enable the self-testing channel by setting STCR2[EN].
5. Program the safe period value in STBRR[WDT].
6. Enable the watchdog timer by setting STAWxR[WDTE]. Assume the setting of WDTE to be t0. (It is important to do all the programming first and to then enable WDTE as the safe time check is also performed between the setting of WDTE and the start of step 0 to check that algorithm has started within the safe time).
7. Start the normal conversion by setting MCR[NSTART].
8. After first chain conversion ends, step 0 of algorithm S is executed. Lets assume the start of STEP0 to be t1.
9. Step 1 and step 2 of algorithm S are executed.
10. The next chain conversions are performed.
11. When chain conversion completes, step 0 of C algorithm is performed.
12. After each chain conversion, a consecutive step of the C algorithm is performed. A similar sequence follows for algorithm C.
13. After the last step of the C algorithm is performed, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S starts, repeating the whole sequence. Let's assume this time (starting of step 0) to be t2.
14. For algorithm S, if (t1 – t0) > Safe Period, or if (t2 – t1) > Safe Period, then the watchdog timer flags an error and STSR1[WDTERR] is set. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDTERR]. Otherwise, the watchdog timer counter is reset and starts again to monitor the same for the next sequence.
15. A similar sequence is followed for watchdog timers for algorithm C.

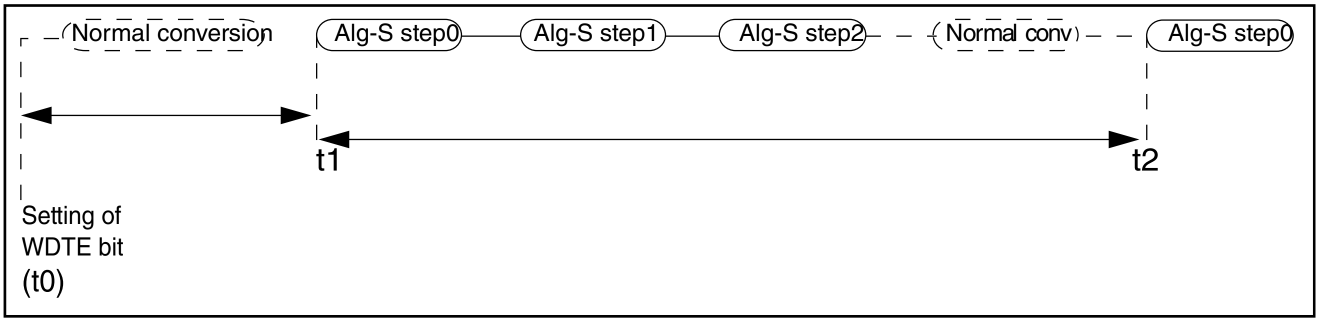


Figure 36-8. Watchdog timer monitor for algorithm S

Notes:

- As CTU does not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for CTU conversions.
- Take care not to enable the watchdog timer for an algorithm that is not to be executed.

36.5.10.2.6.1 Watchdog sequence checking

The watchdog timer also incorporates sequence checking features that check the order of a particular algorithm's steps. If the steps are not in order, then an error is flagged by setting the STSR1[WDSERR]. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDSERR].

A watchdog sequence error is flagged in the following cases:

- If the steps of any algorithm are not executed in the proper order.
- If an abort chain occurs during a test channel conversion, that step has to be repeated at the end of the next chain. This will give a sequence error as soon as test channel conversion starts again.
    - Exception: If an abort chain occurs during the last step of algorithm S, then sequence errors are not flagged as the whole algorithm has to be repeated again.
- If, for CTU conversions, the step numbers provided by the CTU are not in order. Watchdog sequence checking is significant for CTU burst mode only.

If injected conversion occurs during the test channel, watchdog sequence errors are *not* flagged a lthough the ongoing step number is aborted and repeated again.

Note

The watchdog timer feature is applicable only for Scan mode, not for One-Shot mode.

36.5.10.2.7 Baud rate control for test channel

It defines the scheduling of the test channel between normal conversions. The scheduling rate is specified by STBRR[BR].

By default, if the test channel is enabled, one step of the selected algorithm is executed after every chain of normal conversion. The bandwidth consumed by the test channel depends on the number of channels in a normal chain. For example, if there are 100 normal conversions in a chain, then the test channel consumes only 1% of the total bandwidth, which is very small. However, if the number decreases to just four channels, then the bandwidth consumed by the test channel is 25%, which is significant (and may not be desirable as it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the test channel conversion to be performed, not at the end of every chain, but at the end of BR + 1 number of chains. For example, if BR = 5, a single step of the selected algorithm for the test channel is performed after six chain conversions, then the next step is performed at end of the next six chain conversions, and so on. By default, the value of BR is 0.

Notes:

- This feature is applicable only for Scan mode, not for One-Shot mode. STBRR[BR] should be set to 0 for one shot mode.
- To use the baud rate feature in Scan mode, the NCMR register should have nonzero value.

36.5.10.2.7.1 Abort chain when baud rate is non-zero

As previously described, a nonzero value of STBRR[BR] means that the test channel conversion is performed at the end of BR + 1 number of chains. If an abort chain occurs during the chain in which the test channel is scheduled to be converted, then the test channel is converted after the next BR + 1 number of chains.

For example, if STBRR[BR] is programmed to 2, the sequence will be two normal chains (without any test channel conversion) followed by a chain with the test channel converted at the end. Now, if an abort chain occurs during first two chains it is treated as a normal chain abort and the test channel is converted at the end of the third chain only (as the case without any abort chain). But if the abort chain occurs during the third chain in which the test channel is scheduled to be converted, then the test channel is converted after next three chains (that is, at the end of sixth chain, counting from the beginning).

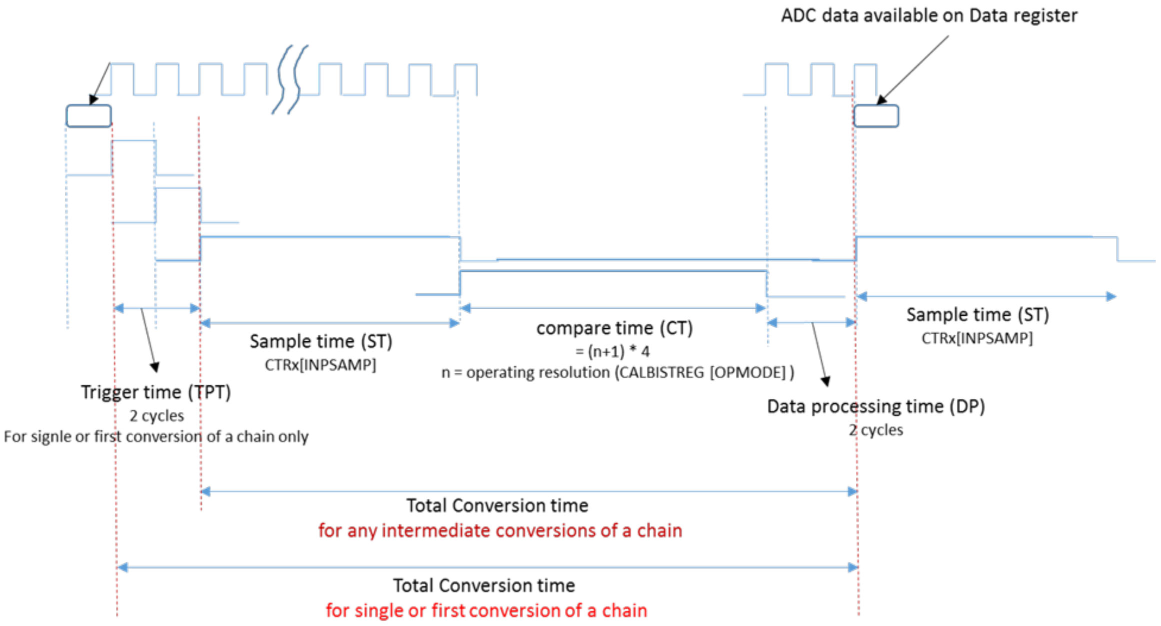
36.5.11 Conversion time

Total conversion time depends on ADC-SAR controller's operating clock. This clock can be prescaled to bus clock ÷ 2. The ADC-SAR operating clock (AD_clk) is always synchronous with bus clock. The frequency of AD_clk is dependent on settings of ADC_MCR[ADCLKSEL].

If ADC_MCR[ADCLKSEL] = 0, then AD_clk = (bus clock ÷ 2)

If ADC_MCR[ADCLKSEL] = 1, then AD_clk = bus clock

The various components of conversion time and affecting configurations are shown and described in Figure 36-9.



ADC data available on Data register
Sample time (ST)
CTRx[INPSAMP]
compare time (CT)
= (n+1) * 4
n = operating resolution (CALBISTREG [OPMODE])
Sample time (ST)
CTRx[INPSAMP]
Trigger time (TPT)
2 cycles
For signle or first conversion of a chain only
Data processing time (DP)
2 cycles
Total Conversion time
for any intermediate conversions of a chain
Total Conversion time
for single or first conversion of a chain

Figure 36-9. Conversion time

- Trigger processing time (TPT):

  To prepare the channel and start the operation, two clock cycles of bus clock is required by the ADC for the first conversion and for subsequent conversions in a chain, or for a continuous conversion, this time is not required as it is hidden in the pipeline operation. Triggers from Synchronous CTU interface requires two cycle of bus clock for first conversion and for back-to-back CTU conversions it takes only one cycle for trigger processing as the other cycle is hidden in pipeline operation. Triggers from Asynchronous CTU interface requires three cycles of bus clock for synchronization and processing.
- Sample phase time (ST):

  Sample time duration is controlled by the INPSAMP[7:0] field of Conversion timing Registers ADC_CTR*x* (*x* = 0...2) for different types of channels. Value in each register affects the sample time in similar way. The value in the register represents units of cycle of the AD_clk. The minium value of sample time is 8. If the value programmed is less than 8, then it has no effect on sample time duration and in this case sample time will be 8 AD_clk cycles.
- Compare phase time (CT):

  The compare phase of the ADC is dependent on the resolution setting. It takes ((n + 1) × 4) cycles of AD_clk, where n is the resolution setting configured in CALBISTREG[OPMODE].

- Data processing time (DP):

The ADC takes 2 cycles of AD_clk to post process and load the data int registers.

- Total Conversion Time:

  The total time required for single or first conversion is [TPT+ST+CT+DP] cycles of AD_clk and for subsequent conversion is a chain or continuous conversion is [ST+CT+DP] cycles of AD_clk.

  Examples:

  - CALBISTREG[OPMODE] = 110b; CTR*x*[INPSAMP] = 20d; software/hardware triggered (NSTART):
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of AD_clk
    - Subsequent/continuous conversion: 20 + ((13 + 1) × 4) + 2 = 20 + 56 + 2 = 78 cycles of AD_clk
  - CALBISTREG[OPMODE] = 001b; CTR*x*[INPSAMP] = 22d; software/hardware triggered (NSTART):
    - Single/First Conversion: 2 + 22 + ((12 + 1) × 4) + 2 = 2 + 22 + 52 + 2 = 78 cycles of AD_clk
    - Subsequent/continuous conversion: 22 + ((12 + 1) × 4) + 2 = 22 + 52 + 2 = 76 cycles of AD_clk
  - CALBISTREG[OPMODE] = 110b; CTR*x*[INPSAMP] = 20d; CTU triggered:
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of AD_clk
    - Subsequent/continuous conversion: 1 + 20 + ((13 + 1) × 4) + 2 = 1 + 20 + 56 + 2 = 79 cycles of AD_clk
  - CALBISTREG[OPMODE] = 001b; CTR*x*[INPSAMP] = 22d; CTU triggered:
    - Single/First Conversion: 2 + 22 + ((12 + 1) × 4) + 2 = 2 + 22 + 52 + 2 = 78 cycles of AD_clk
    - Subsequent/continuous conversion: 1 + 22 + ((12 + 1) × 4) + 2 = 1 + 22 + 52 + 2 = 77 cycles of AD_clk
- Pre-Sampling:

  When pre-sampling is enabled, the ADC does pre-sampling prior to starting the actual channel sampling as described in pre-sampling section. This phase takes CTR*x*[INPSAMP] cycles of AD_clk. Additionally, to switch from pre-sample phase to actual channel sampling phase, it takes another two cycles of AD_clk. So, total CTR*x*[INPSAMP] + 2 cycles additionally required for a conversion to be completed. Thus, in case of pre-sample, all the equations and examples above are valid with the addition of (CTR*x*[INPSAMP] + 2) cycles.

36.5.12 Conversion data processing

The raw converted ADC data contains many types of errors such as offset, gain, DC bias, and so on. Thus, to generate error-free results, raw converted data is processed before it is written to a result register. The process of error correction goes bit-by-bit during conversion with the values generated during the offset calculation and calibration process. This helps in reducing final data processing time as only one addition/addition (2's complement) is performed parallely with conversion.

36.6 Clock frequency

The ADC internal blocks are designed to work with an 80 MHz clock. Thus, the specified speed can be met with this clock frequency. If the clock is faster than this, ADCA cannot work properly and the ADC may malfunction. If the clock is slower, then the ADC speed will be lower, but it will work properly. It should be noted that there is an absolute maximum value of the sampling time that the analog portion of the ADC can support. For slower clocks, the sampling clock count will need to be programmed accordingly.

Chapter 37
Temperature Sensor (TSENS)

37.1 Introduction

The device includes two on-chip temperature sensors. The temperature sensor module monitors device temperature and delivers one analog output signal and three digital output signals each (under- and over-temperature flags). The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device (see the ADC details for the channel number). The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage; sampled bandgap reference voltage, which comes from another module; and calibration parameter values stored in internal flash memory. The three digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions.

The digital outputs signal when the junction temperature drifts below the low temperature threshold or above one of the two high temperature thresholds. These signals notify the device to take action to appropriately adjust the device temperature in response to an out-of-specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

37.2 Functional Description

The temperature sensor generates one analog output voltage, V_{TSENS}(T), which is proportional to the absolute current junction temperature of the device, and three digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or one of two pre-set high temperature thresholds.

An on-chip ADC module is used to convert the analog output voltage, as well as the bandgap reference voltage, into a digital representation. These values, along with parameter values stored in on-chip flash memory, are used by software to calculate the device junction temperature.

37.2.1 Temperature threshold detection (digital output generation)

Temperature threshold trimming values are adjusted through calibration during factory test and stored in on-chip flash memory. While enabled, if a new trimming value is loaded into the Temperature Sensor module, it may take up to 1 microsecond for the digital outputs to be updated to reflect the new trimming condition.

When the temperature threshold detection feature is enabled, the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the following temperature thresholds are crossed.

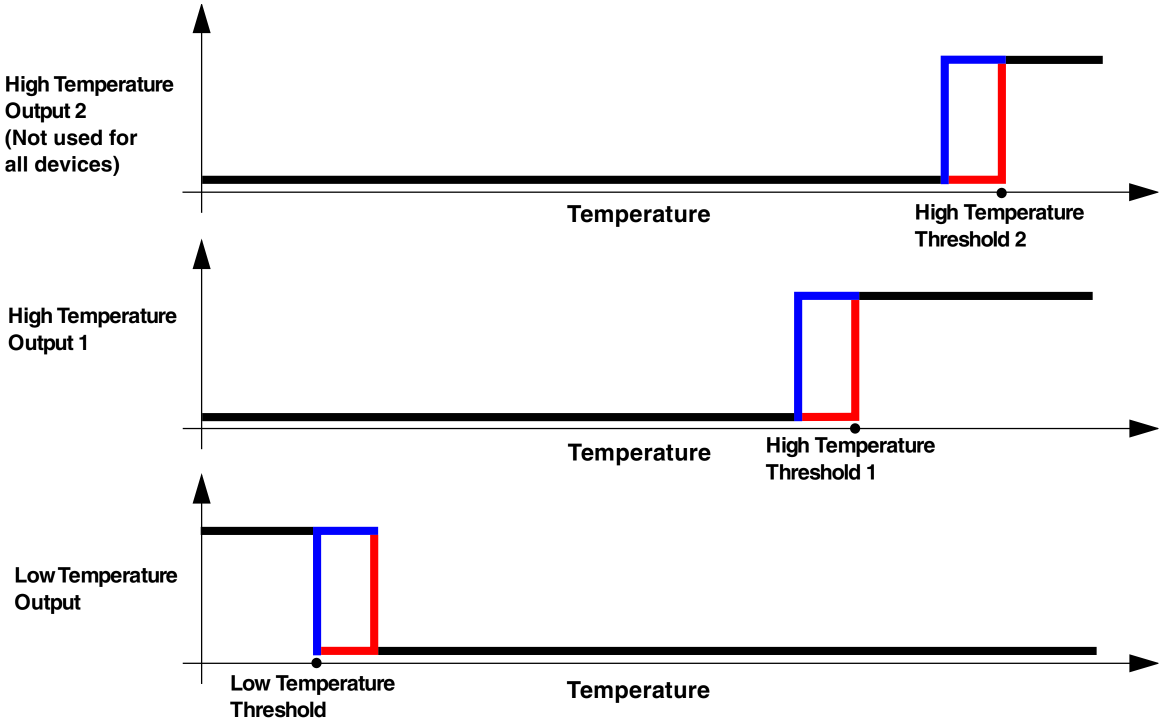
- The low temperature digital output signals if the junction temperature falls below the low temperature threshold (-40°C).
- The high temperature digital output 1 signals if the junction temperature rises above the first high temperature threshold (150°C).
- The high temperature digital output 2 signals if the junction temperature rises above the second high temperature threshold (165°C).

NOTE

Some devices do not support 165°C operation.

The threshold detection circuit is calibrated with respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to –40°C), and the high temperature thresholds are trimmed such that one of them matches the hot insertion test temperature (nominally equal to 150°C or 165°C). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated on Figure 37-1.



High Temperature Output 2 (Not used for all devices)

Temperature

Figure 37-1. Digital output behavior with temperature

37.2.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

37.3 Temperature formula

The system chain that translates device junction temperature into a digital variable is composed of the temperature sensor, a bandgap reference voltage source and the on-chip ADC. Both analog output voltages of the temperature sensor and the bandgap reference voltage source must be converted by the ADC into digital codes to obtain the device junction temperature. The temperature formula shown in Figure 37-2 is used to calculate internal device junction temperature.

$$T \times 2^{2} = \frac{(K_{1} \times V_{BG\_CODE}(T)) \times 2^{-1} + (K_{2} \times V_{TSENS\_CODE}(T)) \times 2^{3}}{[(K_{3} \times V_{BG\_CODE}(T)) \times 2^{2} + (K_{4} \times V_{TSENS\_CODE}(T))] \times 2^{-10}} \quad [K]$$

$$V_{TSENS\_CODE}(T) = \frac{V_{TSENS}(T)}{V_{ref}} \times 2^{12} \qquad V_{BG\_CODE}(T) = \frac{V_{BG}(T)}{V_{ref}} \times 2^{12}$$

- T is the internal junction temperature in Kelvin
- $V_{TSENS}(T)$ is the temperature sensor output sampled by the ADC
- $V_{BG}(T)$ is the bandgap reference voltage sampled by the ADC
- V_{ref} is the ADC reference voltage in normal usage of the device
- K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation stored in flash memory (obtained from factory calibration)

Figure 37-2. Temperature formula

Parameters K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation that are stored in flash memory during factory test and calibration. These constants must be used in the temperature formula to calculate device junction temperature.

37.4 Calculating device temperature

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap reference voltage using the on-chip ADC module and calculate $V_{BG\_CODE}(T)$ according to the formula shown in Figure 37-2.
2. Measure the temperature sensor output voltage using the on-chip ADC module and calculate $V_{TSENS\_CODE}(T)$ according to the formula shown in Figure 37-2
3. Retrieve parameters K1, K2, K3, and K4 from flash memory.
4. Calculate T according to the formula shown in Figure 37-2.

Note

Temperature Formula may be calculated using signed 32-bit (integer) operations showing negligible precision loss.

Chapter 38
Sine Wave Generator (SGEN)

38.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Sine Wave Generator (SGEN) generates a high-quality sinusoidal voltage signal. It can be programmed with the desired oscillation frequency and amplitude voltage. A wide frequency range (1 kHz–50 kHz in 16 Hz steps) is easily programmable through a simple register interface. The linearity and noise performance is carefully optimized through digital processing.

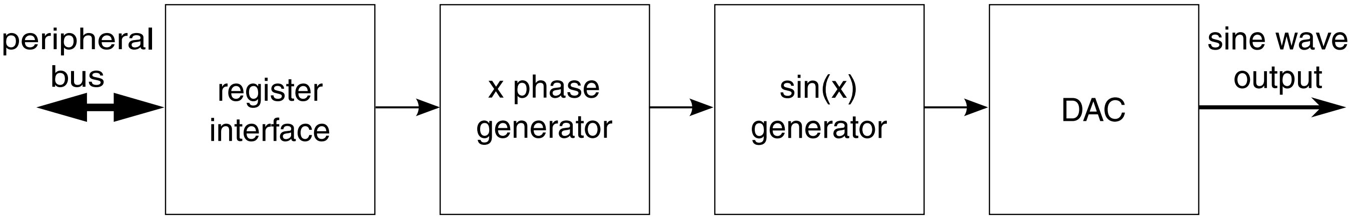

Figure 38-1. SGEN block diagram

38.2 Features

- Input clock frequency range: 12 MHz–20 MHz
- Output sinusoidal signal:
  - Frequency range: 1 kHz–50 kHz
  - Peak-to-peak amplitude: user adjustable

38.3 Memory map and register description

The SGEN memory map is shown below followed by the description for each register and its fields.

SGEN memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control Register (SGEN_CTRL)	32	R/W	0001_0000h	38.3.1/1068
4	Status Register (SGEN_STAT)	32	R/W	0000_0000h	38.3.2/1070

38.3.1 Control Register (SGEN_CTRL)

The SGEN_CTRL register enables the following operations:

- Control and read the output sine wave frequency.
- Control and read the output sine wave amplitude.
- Enable and disable the input trigger to align the phase of the sine wave output.
- Select the active trigger input for phase alignment.

Address: 0h base + 0h offset = 0h

SGEN_STAT field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SERR	Error interrupt status This field is set only by the chip and not by software. It can be cleared in software by writing a 1 to it. During an SGEN_STAT[SERR] clear operation, the hardware set is not allowed to set this field. **NOTE:** This field is set on either of the following conditions: • There is an error in the demodulator block. • The input trigger's phase is out of the 1% window of the current sine wave output. 0 No error interrupt pending 1 Error interrupt pending
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FERR	Force error interrupt **NOTE:** Because this field is set in the bus clock domain and the SGEN digital block operates in the SGEN clock domain, both clocks must be present to set the SGEN_STAT[SERR] field. Also, due to the synchronization between two asynchronous clocks, the setting of SGEN_STAT[SERR] will

Table continues on the next page...

SGEN_STAT field descriptions (continued)

Field	Description
	occur, at maximum, 4 bus clock and 4 SGEN clock cycles after the setting of SGEN_STAT[FERR]. 0 An error interrupt will not be forced. 1 An error interrupt will be forced.
13 PHERR	Phase error SERR will be set when this field transistions from 0 to 1. This field can be reset to 0 by software.
14–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

38.4 Functional description

38.4.1 Operation after a power-on reset

After a power-on reset, the SGEN produces a DC value (no sinusoidal fluctuations).

38.4.2 Output sine wave frequency

The output sine wave frequency *f* is controlled by SGEN_CTRL[IOFREQ] according to Equation 16 on page 1071 where frequencies *f* and InputFrequency are in Hz, and IOFREQ is in decimal format. IOFREQ must be chosen to ensure that *f* remains between 1 kHz and 50 kHz.

$$f = \frac{\mathrm{InputFrequency}}{1048576} \times \mathrm{IOFREQ}$$

Equation 16. Output sine wave frequency

38.4.3 Output sine wave amplitude

The amplitude of the output sine wave is controlled by SGEN_CTRL[IOAMPL] as described in the following table.

Table 38-1. Resulting sine wave amplitude for each IOAMPL value

IOAMPL value (decimal)	Sine wave amplitude (V)	Sine wave amplitude step (V)
0	0.423	
1	0.487	0.064

Table continues on the next page...

Table 38-1. Resulting sine wave amplitude for each IOAMPL value (continued)

IOAMPL value (decimal)	Sine wave amplitude (V)	Sine wave amplitude step (V)
2	0.550	0.063
3	0.613	0.063
4	0.675	0.062
5	0.737	0.062
6	0.797	0.060
7	0.857	0.060
8	0.987	0.130
9	1.136	0.149
10	1.284	0.148
11	1.430	0.146
12	1.575	0.145
13	1.719	0.144
14	1.861	0.142
15	2.00	0.139

38.5 Initialization and application information

38.5.1 Changing the output frequency

To change the output frequency:

1. Determine the required value of SGEN_CTRL[IOFREQ] using Equation 16 on page 1071.
2. Ensure that SGEN_CTRL[LDOS] = 0.
3. Write the new value of the SGEN_CTRL[IOFREQ] field.
4. Set SGEN_CTRL[LDOS].

The SGEN will begin producing the new sine wave frequency two input clock cycles after this procedure is completed.

38.5.2 Phase control of the sine wave output

The normal output of the sine wave generator is a free-running sine wave with the amplitude and frequency determined by the SGEN_CTRL register settings. SGEN_CTRL[TRIG_EN] enables the user to phase align the sine wave output to one of the trigger inputs, which is selected by SGEN_CTRL[TRIG_SEL]. The trigger input is a periodic signal which has the same fequency as the sine wave output but might have a different phase, either leading or lagging. The phase of the trigger input signal is compared to the phase the sine wave output. If a phase offset is detected, the sine wave output is realigned so that the phase difference becomes zero, beginning with the next sine wave cycle.

If the phase difference of the trigger input varies more than 1%, either leading or lagging, from sine wave output, no phase adjustment will take place. Instead, SGEN_STAT[SERR] will be set indicating that the phase offset has exceeded 1%. In this case, the sine wave output will not be re-generated.

NOTE

- Because the trigger input is an asynchronous signal, it must be held high for at least 2 SGEN clock cycles in order to capture the input trigger. This requirement must be guaranteed by the module generating the trigger input signal. If this requirement is not met, phase alignment will not function as expected.
- When SGEN_CTRL[TRIG_EN] is set, the sine wave output will not be generated until the first trigger occurs.
- If the actual trigger position falls in the +/- 1% range, the sine wave output will be aligned to the trigger beginning with the next period.

38.5.3 Preserving the SGEN_CTRL data

Changes made to the SGEN_CTRL register must be preserved for at least 50 clock cycles. Failure to do so might cause unexpected output from the SGEN.

Chapter 39
Enhanced Motor Control Timer (eTimer)

39.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section briefly describes the eTimer, its features and customization, and contains block diagrams.

39.1.1 Overview

An eTimer module provides:

- Six identical counter/timer channels
- One watchdog timer function (might not be available on every eTimer module instance)

Each 16-bit counter/timer channel contains a prescaler, a counter, a load register, a hold register, two queued capture registers, two compare registers, two compare preload registers, and four control registers.

Note

> This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The Load register provides the initialization value to the counter when the counter's terminal value has been reached. For true modulo counting the counter can also be initialized by the CMPLD1 or CMPLD2 registers.

The Hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters coherently.

The Capture registers enable an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG signal can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The Prescaler provides different time bases useful for clocking the counter/timer.

The Counter provides the ability to count internal or external events.

Within the eTimer module, the input pins are shareable.

39.1.2 Features

The eTimer module design includes these distinctive features:

- 16-bit counters/timers: Six.
- Count up/down.
- Counters are cascadable.
- Enhanced programmable up/down modulo counting.
- Max count rate equals peripheral clock/2 for external clocks.
- Max count rate equals peripheral clock for internal clocks.
- Count once or repeatedly.
- Counters are preloadable.
- Compare registers are preloadable.
- Counters can share available input pins.
- Separate prescaler for each counter.
- Each counter has capture and compare capability.
- Continuous and single shot capture for enhanced speed measurement.
- DMA support of capture registers and compare registers.
- 32-bit watchdog capability to detect stalled quadrature counting (might not be available on every eTimer module instance).
- OFLAG comparison for safety critical applications.
- Programmable operation during debug mode and stop mode.
- Programmable input filter.
- Counting start can be synchronized across counters.

39.1.3 Module block diagram

The eTimer block diagram is shown in the following figure.

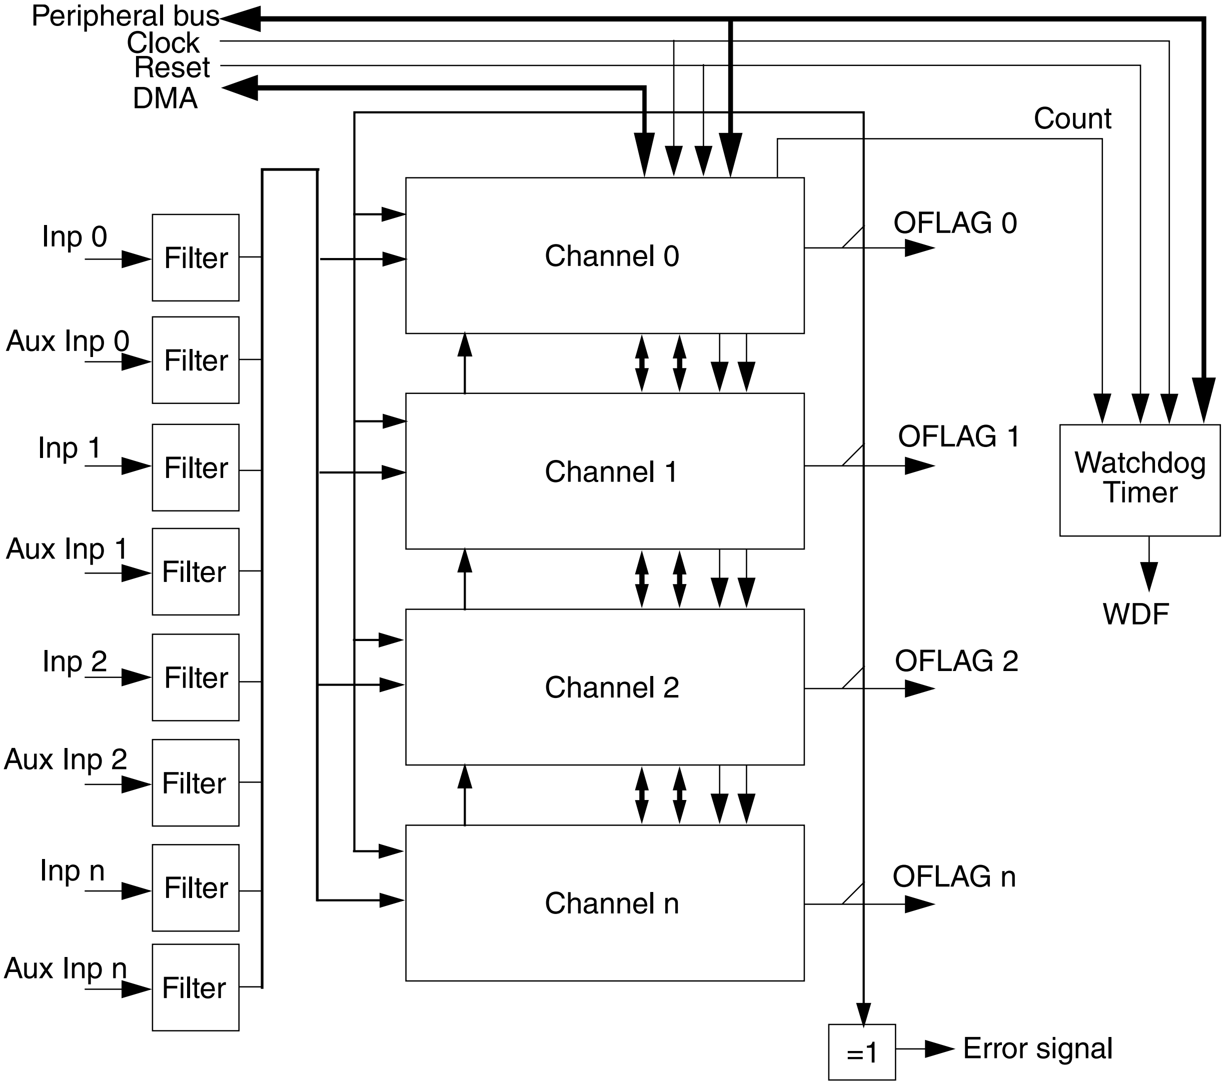

Figure 39-1. eTimer Block Diagram

39.1.4 Channel Block Diagram

Each of the timer/counter channels within the eTimer are shown in the following figure.

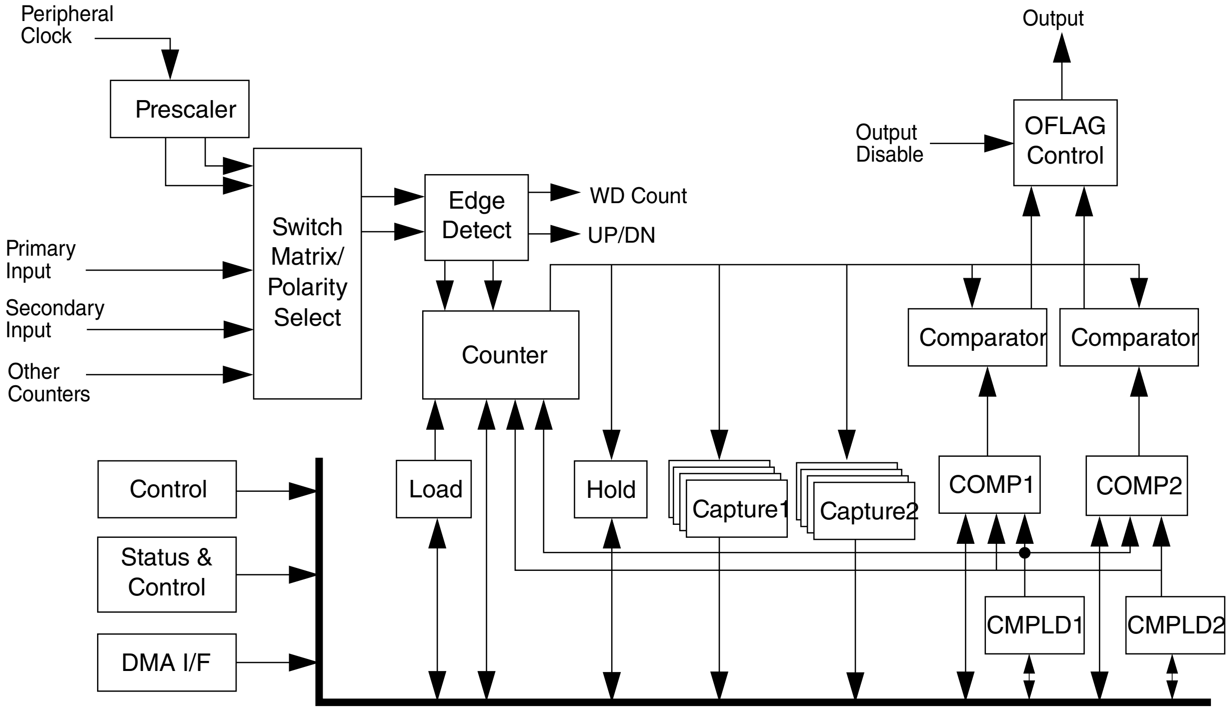

Figure 39-2. eTimer Channel Block Diagram

39.2 External Signal Descriptions

Each eTimer module has six external signals that can be used as either inputs or outputs. The number of auxilliary inputs per module is device-dependent. See the configuration section for more information. The eTimer also interfaces to the Peripheral Bus.

39.2.1 TIO[n:0] - Timer Input/Outputs

These pins can be independently configured to be either timer input sources or output flags. In Figure 39-2, the TIO signals are shown as the Primary Inputs, and the Outputs from the OFLAG Control block.

39.2.2 TAI[n:0] - Timer Auxiliary Inputs

These pins act as alternate input choices for the timer channels. The TAI signals are shown as Aux Inp 1..n in .

39.3 Memory map and register definition

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. There are a set of registers for each timer channel, a set for the watchdog timer, and a set of configuration registers. Certain registers are labelled as not byte accessible. However, no error is generated if a byte access occurs.

The base address of the Watchdog Timer registers is equal to the base address of the eTimer plus an offset of 100h.

39.3.1 Channel n Compare Register 1 (ETIMER_CH*n*_COMP1)

This read/write register stores the value used for comparison with the counter value. This register is not byte accessible. More explanation on the use of COMP1 can be found in Usage of Compare Registers .

Address: 0h base + 0h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	COMP1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_COMP1 field descriptions

Field	Description
0–15 COMP1	Value used for comparison with the counter value

39.3.2 Channel n Compare Register 2 (ETIMER_CH*n*_COMP2)

This read/write register stores the value used for comparison with the counter value. This register is not byte accessible. More explanation on the use of COMP2 can be found in Usage of Compare Registers .

Address: 0h base + 2h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	COMP2															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_COMP2 field descriptions

Field	Description
0–15 COMP2	Value used for comparison with the counter value

39.3.3 Channel n Capture Register 1 (ETIMER_CH*n*_CAPT1)

This read-only register stores the value captured from the counter. It is actually a 2-deep FIFO and not a single register. This register is not byte accessible. CCCTRL[CPT1MODE] determines when a capture occurs.

Address: 0h base + 4h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_LOAD field descriptions

Field	Description
0–15 LOAD	Value used to initialize the counter

39.3.6 Channel n Hold Register (ETIMER_CH*n*_HOLD)

This read-only register stores the counter's value whenever any of the counters within a module are read. This is used to support coherent reading of cascaded counters.

Address: 0h base + Ah offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	HOLD															
Write	▨															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_HOLD field descriptions

Field	Description
0–15 HOLD	Stores the counter's value whenever any of the counters within a module are read.

39.3.7 Channel n Counter Register (ETIMER_CH*n*_CNTR)

This read/write register is the counter for this channel of the timer module. This register is not byte accessible.

Address: 0h base + Ch offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CNTR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CNTR field descriptions

Field	Description
0–15 CNTR	Counter for this channel of the timer module

39.3.8 Channel n Control Register 1 (ETIMER_CH*n*_CTRL1)

Address: 0h base + Eh offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7
Read Write	CNTMODE			PRISRC				
Reset	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CTRL1 field descriptions

Field	Description
0–2 CNTMODE	Count mode These bits control the basic counting and behavior of the counter. 000 No Operation 001 Count rising edges of primary source (Rising edges counted only when PIPS = 0. Falling edges counted when PIPS = 1. If primary count source is IP bus clock, only rising edges are counted regardless of PIPS value.) 010 Count rising and falling edges of primary source (IP Bus clock divide by 1 can not be used as a primary count source in edge count mode.) 011 Count rising edges of primary source while secondary input high active 100 Quadrature count mode, uses primary and secondary sources 101 Count primary source rising edges, secondary source specifies direction (1 = minus) (Rising edges counted only when PIPS = 0. Falling edges counted when PIPS = 1.)

Table continues on the next page...

ETIMER_CH*n*_CTRL1 field descriptions (continued)

Field	Description
	110 Edge of secondary source triggers primary count till compare 111 Cascaded counter mode, up/down (Primary count source must be set to one of the counter outputs.)
3–7 PRISRC	Primary Count Source These bits select the primary count source. **NOTE:** A timer selecting its own output as its primary count source is not a legal choice. The result is no counting. — 00000 Counter #0 input pin 00001 Counter #1 input pin 00010 Counter #2 input pin 00011 Counter #3 input pin 00100 Counter #4 input pin 00101 Counter #5 input pin 00110 Reserved 00111 Reserved 01000 Auxiliary input #0 pin 01001 Auxiliary input #1 pin 01010 Auxiliary input #2 pin 01011 Auxiliary input #3 pin 01100 Auxiliary input #4 pin 01101 Reserved 01110 Reserved 01111 Reserved 10000 Counter #0 output 10001 Counter #1 output 10010 Counter #2 output 10011 Counter #3 output 10100 Counter #4 output 10101 Counter #5 output 10110 Reserved 10111 Reserved 11000 IP Bus clock divide by 1 prescaler 11001 IP Bus clock divide by 2 prescaler 11010 IP Bus clock divide by 4 prescaler 11011 IP Bus clock divide by 8 prescaler 11100 IP Bus clock divide by 16 prescaler 11101 IP Bus clock divide by 32 prescaler 11110 IP Bus clock divide by 64 prescaler 11111 IP Bus clock divide by 128 prescaler
8 ONCE	Count once This bit selects continuous or one shot counting mode.

Table continues on the next page...

ETIMER_CH*n*_CTRL1 field descriptions (continued)

Field	Description
	0 Count repeatedly. 1 Count until compare and then stop. When output mode 4h is used, the counter re-initializes after reaching the COMP1 value and continues to count to the COMP2 value then stops.
9 LENGTH	Count Length This bit determines whether the counter counts to the compare value and then re-initializes itself to the value specified in the LOAD, CMPLD1, or CMPLD2 registers, or the counter continues counting past the compare value, to the binary roll over. 0 Continue counting to roll over. 1 Count until compare, then reinitialize. The value that the counter is reinitialized with depends on the settings of CLC1 and CLC2. If neither of these indicates the counter is to be loaded from one of the CMPLD registers, then the LOAD register is used to reinitialize the counter upon matching either COMP register. If one of CLC1 or CLC2 indicates that the counter is to be loaded from one of the CMPLD registers, then the counter will reinitialize to the value in the appropriate CMPLD register upon a match with the appropriate COMP register. If both of the CLC1 and CLC2 fields indicate that the counter is to be loaded from the CMPLD registers, then CMPLD1 will have priority if both compares happen at the same value. When output mode 4h is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until COMP1 value is reached, re-initializes, then counts until COMP2 value is reached, re-initializes, then counts until COMP1 value is reached, etc.
10 DIR	Count Direction This bit selects either the normal count direction up, or the reverse direction, down. 0 Count up 1 Count down
11–15 SECSRC	Secondary Count Source These bits identify the source to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of the CNTR register. The selected input can also be used to specify the count direction. The polarity of the signal can be inverted by the SIPS bit of the CTRL2 register. 00000 Counter #0 input pin 00001 Counter #1 input pin 00010 Counter #2 input pin 00011 Counter #3 input pin 00100 Counter #4 input pin 00101 Counter #5 input pin 00110 Reserved 00111 Reserved 01000 Auxiliary input #0 pin 01001 Auxiliary input #1 pin 01010 Auxiliary input #2 pin 01011 Auxiliary input #3 pin 01100 Auxiliary input #4 pin 01101 Reserved 01110 Reserved 01111 Reserved 10000 Counter #0 output 10001 Counter #1 output

39.3.9 Channel n Control Register 2 (ETIMER_CH*n*_CTRL2)

Address: 0h base + 10h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7
Read	OEN	RDNT	INPUT	VAL	0	COFRC	COINIT	
Write			▨		FORCE			
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	SIPS	PIPS	OPS	MSTR	OUTMODE			
Write								
Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CTRL2 field descriptions

Field	Description
0 OEN	Output Enable This bit determines the direction of the external pin. 0 The external pin is configured as an input. 1 OFLAG output signal will be driven on the external pin. Other timer channels using this external pin as their input will see the driven value. The polarity of the signal will be determined by the OPS bit.
1 RDNT	Redundant Channel Enable This bit enables redundant channel checking between adjacent channels (0 and 1, 2 and 3, 4 and 5). When this bit is clear, the RCF bit in this channel cannot be set. When this bit is set, the RCF bit will be set by a miscompare between the OFLAG of this channel and the OFLAG of its redundant adjacent channel which will cause the output of this channel to go inactive (logic 0 prior to consideration of the OPS bit). 0 Disable redundant channel checking. 1 Enable redundant channel checking.
2 INPUT	External input signal This read only bit reflects the current state of the signal selected via SECSRC after application of the SIPS bit and filtering.
3 VAL	Forced OFLAG Value

Table continues on the next page...

ETIMER_CH*n*_CTRL2 field descriptions (continued)

Field	Description
	This bit determines the value of the OFLAG output signal when a software triggered FORCE command occurs.
4 FORCE	Force the OFLAG output This write only bit forces the current value of the VAL bit to be written to the OFLAG output. This bit always reads as a zero. The VAL and FORCE bits can be written simultaneously in a single write operation. Write to the FORCE bit only if OUTMODE is 0000 (software controlled). Setting this bit while the OUTMODE is a different value may yield unpredictable results.
5 COFRC	Co-channel OFLAG Force This bit enables the compare from another channel within the module to force the state of this counter's OFLAG output signal. 0 Other channels cannot force the OFLAG of this channel. 1 Other channels may force the OFLAG of this channel.
6–7 COINIT	Co-channel Initialization These bits enable another channel within the module to force the re-initialization of this channel when the other channel has an active compare event. 00 Other channels cannot force re-initialization of this channel. 01 Other channels may force a re-initialization of this channel's counter using the LOAD reg. 10 Other channels may force a re-initialization of this channel's counter with the CMPLD2 reg when this channel is counting down or the CMPLD1 reg when this channel is counting up. 11 Reserved
8 SIPS	Secondary Source Input Polarity Select This bit inverts the polarity of the signal selected by the SECSRC bits. 0 True polarity. 1 Inverted polarity.
9 PIPS	Primary Source Input Polarity Select This bit inverts the polarity of the signal selected by the PRISRC bits. This only applies if the signal selected by PRISRC is not the prescaled IP Bus clock. 0 True polarity. 1 Inverted polarity.
10 OPS	Output Polarity Select. This bit inverts the OFLAG output signal polarity. 0 True polarity. 1 Inverted polarity.
11 MSTR	Master Mode This bit enables the compare function's output to be broadcasted to the other channels in the module. The compare signal then can be used to reinitialize the other counters and/or force their OFLAG signal outputs. 0 Disable broadcast of compare events from this channel. 1 Enable broadcast of compare events from this channel.

Table continues on the next page...

ETIMER_CH*n*_CTRL2 field descriptions (continued)

Field	Description
12–15 OUTMODE	Output Mode These bits determine the mode of operation for the OFLAG output signal. 0000 Software controlled 0001 Clear OFLAG output on successful compare (COMP1 or COMP2) 0010 Set OFLAG output on successful compare (COMP1 or COMP2) 0011 Toggle OFLAG output on successful compare (COMP1 or COMP2) 0100 Toggle OFLAG output using alternating compare registers 0101 Set on compare with COMP1, cleared on secondary source input edge 0110 Set on compare with COMP2, cleared on secondary source input edge 0111 Set on compare, cleared on counter roll-over 1000 Set on successful compare on COMP1, clear on successful compare on COMP2 1001 Asserted while counter is active, cleared when counter is stopped. 1010 Asserted when counting up, cleared when counting down. 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Enable gated clock output while counter is active

39.3.10 Channel n Control Register 3 (ETIMER_CH*n*_CTRL3)

Address: 0h base + 12h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7
Read Write	STPEN	ROC		Reserved				
Reset	0	0	0	0	1	1	1	1

Write	▨	▨	▨	▨	▨	▨		
Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CTRL3 field descriptions

Field	Description
0 STPEN	Stop Actions Enable This bit allows the tri-stating of the timer output during stop mode. 0 Output enable is unaffected by stop mode. 1 Output enable is disabled during stop mode.
1–2 ROC	Reload on Capture

Table continues on the next page...

ETIMER_CH*n*_CTRL3 field descriptions (continued)

Field	Description
	These bits enable the capture function to cause the counter to be reloaded from the LOAD register. 00 Do not reload the counter on a capture event. 01 Reload the counter on a capture 1 event. 10 Reload the counter on a capture 2 event. 11 Reload the counter on both a capture 1 event and a capture 2 event.
3–7 Reserved	This field is reserved.
8–10 C2FCNT	Capture 2 FIFO count This field reflects the number of words in the CAPT2 FIFO.
11–13 C1FCNT	Capture 1 FIFO count This field reflects the number of words in the CAPT1 FIFO.
14–15 DBGEN	Debug Actions Enable These bits allow the counter channel to perform certain actions in response to the chip entering debug mode. 00 Continue with normal operation during debug mode. (default) 01 Halt channel counter during debug mode. 10 Force OFLAG to logic 0 (prior to consideration of the OPS bit) during debug mode. 11 Both halt counter and force OFLAG to 0 during debug mode.

39.3.11 Channel n Status Register (ETIMER_CH*n*_STS)

Address: 0h base + 14h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						WDF	RCF	ICF2	ICF1	IEHF	IELF	TOF	TCF2	TCF1	TCF
Write							w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_STS field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 WDF	Watchdog Time-out Flag This bit is set when the watchdog times out by counting down to zero. The watchdog must be enabled for time-out to occur and channel 0 must be in quadrature decode count mode (CNTMODE = 100). This bit is cleared by writing a 1 to this bit position after either writing a non-zero value to WDTOL and/or WDTOH or exiting quadrature decode counting mode. This bit is only in channel 0. If the watchdog timer is not implemented, then this bit is read-only zero.
7 RCF	Redundant Channel Flag

Table continues on the next page...

ETIMER_CHn_STS field descriptions (continued)

Field	Description
	This field is set to 1 when there is a miscompare between this channel's OFLAG value and the OFLAG value of the corresponding redundant channel. Corresponding channels are grouped together in the following pairs: 0 and 1, 2 and 3, 4 and 5 . This field can only be set to 1 if the RDNT bit is set. This field is cleared by writing a 1 to this field. **NOTE:** This field is functional only in the even channels, i.e., 0, 2, 4 . In the odd channels, this field cannot create an interrupt.
8 ICF2	Input Capture 2 Flag This bit is set when an input capture event (as defined by CPT2MODE) occurs and the word count of the CAPT2 FIFO exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF2DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF2DE is set (DMA).
9 ICF1	Input Capture 1 Flag This bit is set when an input capture event (as defined by CPT1MODE) occurs and the word count of the CAPT1 FIFO exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF1DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF1DE is set (DMA).
10 IEHF	Input Edge High Flag This bit is set when a positive input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.
11 IELF	Input Edge Low Flag This bit is set when a negative input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.
12 TOF	Timer Overflow Flag This bit is set when the counter rolls over its maximum value FFFFh or 0000h (depending on count direction). This bit is cleared by writing a one to this bit location.
13 TCF2	Timer Compare 2 Flag This bit is set when a successful compare occurs with COMP2. This bit is cleared by writing a one to this bit location.
14 TCF1	Timer Compare 1 Flag This bit is set when a successful compare occurs with COMP1. This bit is cleared by writing a one to this bit location.
15 TCF	This bit is set when a successful compare occurs. This bit is cleared by writing a one to this bit location.

39.3.12 Channel n Interrupt and DMA Enable Register (ETIMER_CH*n*_INTDMA)

Address: 0h base + 16h offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7
Read	ICF2DE	ICF1DE	CMPLD2DE	CMPLD1DE	0		WDFIE	RCFIE
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_INTDMA field descriptions

Field	Description
0 ICF2DE	Input Capture 2 Flag DMA Enable Setting this bit enables DMA read requests for CAPT2 when the ICF2 bit is set. Do not set both this bit and the ICF2IE bit.
1 ICF1DE	Input Capture 1 Flag DMA Enable Setting this bit enables DMA read requests for CAPT1 when the ICF1 bit is set. Do not set both this bit and the ICF1IE bit.
2 CMPLD2DE	Comparator Load Register 2 Flag DMA Enable Setting this bit enables DMA write requests to the CMPLD2 register whenever data is transferred out of the CMPLD2 reg into either the CNTR, COMP1, or COMP2 registers.
3 CMPLD1DE	Comparator Load Register 1 Flag DMA Enable Setting this bit enables DMA write requests to the CMPLD1 register whenever data is transferred out of the CMPLD1 reg into either the CNTR, COMP1, or COMP2 registers.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 WDFIE	Watchdog Flag Interrupt Enable Setting this bit enables interrupts when the WDF bit is set. This bit is only in channel 0. If the watchdog timer is not implemented, then this bit serves no purpose.
7 RCFIE	Redundant Channel Flag Interrupt Enable Setting this bit enables interrupts when the RCF bit is set. This bit is only in even channels (0, 2, and 4).
8 ICF2IE	Input Capture 2 Flag Interrupt Enable Setting this bit enables interrupts when the ICF2 bit is set. Do not set both this bit and the ICF2DE bit.
9 ICF1IE	Input Capture 1 Flag Interrupt Enable Setting this bit enables interrupts when the ICF1 bit is set. Do not set both this bit and the ICF1DE bit.
10 IEHFIE	Input Edge High Flag Interrupt Enable Setting this bit enables interrupts when the IEHF bit is set.

Table continues on the next page...

ETIMER_CH*n*_INTDMA field descriptions (continued)

Field	Description
11 IELFIE	Input Edge Low Flag Interrupt Enable Setting this bit enables interrupts when the IELF bit is set.
12 TOFIE	Timer Overflow Flag Interrupt Enable Setting this bit enables interrupts when the TOF bit is set.
13 TCF2IE	Timer Compare 2 Flag Interrupt Enable Setting this bit enables interrupts when the TCF2 bit is set.
14 TCF1IE	Timer Compare 1 Flag Interrupt Enable Setting this bit enables interrupts when the TCF1 bit is set.
15 TCFIE	Timer Compare Flag Interrupt Enable Setting this bit enables interrupts when the TCF bit is set.

39.3.13 Channel n Comparator Load Register 1 (ETIMER_CH*n*_CMPLD1)

This read/write register is the preload value for the COMP1 register. This register can also be used to load into the CNTR register. This register is not byte accessible. More information on the use of this register can be found in Usage of Compare Load Registers .

Address: 0h base + 18h offset + (32d × i), where i=0d to 5d

Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CCCTRL field descriptions

Field	Description
0–2 CLC2	Compare Load Control 2 These bits control when COMP2 is preloaded. It also controls the loading of CNTR. 000 Never preload 001 Reserved 010 Load COMP2 with CMPLD1 upon successful compare with the value in COMP1. 011 Load COMP2 with CMPLD1 upon successful compare with the value in COMP2. 100 Load COMP2 with CMPLD2 upon successful compare with the value in COMP1. 101 Load COMP2 with CMPLD2 upon successful compare with the value in COMP2.

Table continues on the next page...

ETIMER_CH*n*_CCCTRL field descriptions (continued)

Field	Description
	110 Load CNTR with CMPLD2 upon successful compare with the value in COMP1. 111 Load CNTR with CMPLD2 upon successful compare with the value in COMP2.
3–5 CLC1	Compare Load Control 1 These bits control when COMP1 is preloaded. It also controls the loading of CNTR. 000 Never preload 001 Reserved 010 Load COMP1 with CMPLD1 upon successful compare with the value in COMP1. 011 Load COMP1 with CMPLD1 upon successful compare with the value in COMP2. 100 Load COMP1 with CMPLD2 upon successful compare with the value in COMP1. 101 Load COMP1 with CMPLD2 upon successful compare with the value in COMP2. 110 Load CNTR with CMPLD1 upon successful compare with the value in COMP1. 111 Load CNTR with CMPLD1 upon successful compare with the value in COMP2.
6–7 CMPMODE	Compare Mode These bits control when the COMP1 and COMP2 registers are used in regards to the counting direction. 00 COMP1 register is used when the counter is counting up; COMP2 register is used when the counter is counting up. 01 COMP1 register is used when the counter is counting down; COMP2 register is used when the counter is counting up. 10 COMP1 register is used when the counter is counting up. COMP2 register is used when the counter is counting down. 11 COMP1 register is used when the counter is counting down; COMP2 register is used when the counter is counting down.
8–9 CPT2MODE	Capture 2 Mode Control These bits control the operation of the CAPT2 register as well as the operation of the ICF2 flag by defining which input edges cause a capture event. The input source is the secondary count source. 00 Disabled 01 Capture falling edges 10 Capture rising edges. 11 Capture any edge.
10–11 CPT1MODE	Capture 1 Mode Control These bits control the operation of the CAPT1 register as well as the operation of the ICF1 flag by defining which input edges cause a capture event. The input source is the secondary count source. 00 Disabled 01 Capture falling edges 10 Capture rising edges. 11 Capture any edge.
12–13 CFWM	Capture FIFO Water Mark This field represents the water mark level for the CAPT1 and CAPT2 FIFOs. The capture flags, ICF1 and ICF2, won't be set until the word count of the corresponding FIFO is equal to or greater than this water mark level.
14 ONESHOT	One Shot Capture Mode This bit selects between free running and one shot mode for the input capture circuitry.

Table continues on the next page...

ETIMER_CH*n*_CCCTRL field descriptions (continued)

Field	Description
	0 Free running mode is selected. If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and capture circuit 1 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1 One shot mode is selected. If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and the ARM bit is cleared. No further captures will be performed until the ARM bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARM bit is then cleared.
15 ARM	Arm Capture Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s). 0 Input capture operation is disabled. 1 Input capture operation as specified by the CPT1MODE and CPT2MODE bits is enabled.

39.3.16 Channel n Input Filter Register (ETIMER_CH*n*_FILT)

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any eTimer channel can use the input as a count source. The FILT register is also used to control the filtering of the corresponding auxilliary input if one exists.

The FILT_PER value should be set such that the sampling period is larger the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT + 3 power.

The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of: (((FILT_CNT + 3) x FILT_PER) + 2) peripheral clock periods.

Address: 0h base + 1Eh offset + (32d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Write	▨															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_FILT field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 FILT_CNT	Input Filter Sample Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in this section.
8–15 FILT_PER	Input Filter Sample Period These bits represent the sampling period (in peripheral clock cycles) of the eTimer input signal. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is $00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in in this section.

39.3.17 Watchdog Time-out Low Word Register (ETIMER_WDTOL)

The fields in WDTOL and WDTOH are combined to form the 32 bit time-out count, WDTO, for the Timer watchdog function. This time-out count is used to monitor for inactivity on the inputs when channel 0 is in the quadrature decode count mode. The watchdog function is enabled whenever WDTO contains a non-zero value (although actual counting only occurs if channel 0 is in quadrature decode counting mode). The watchdog time-out down counter is loaded whenever WDTOH is written. This register is not byte accessible. See Watchdog Timer for more information on the use of the watchdog timer.

Address: 0h base + 100h offset = 100h

39.4 Functional Description

This section provides a functional description of eTimer.

39.4.1 General

Each channel has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.

- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
    - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the channels within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be "captured"
- They can be used to generate interrupt requests

The polarity of the external inputs is selectable.

The primary output of each channel is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is programmable.

Any channel can be assigned as a "Master". A master's compare signal can be broadcasted to the other channels within the module. The other channels can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a Master channel's compare event occurs.

39.4.2 Counting Modes

The selected external signals are sampled at the eTimer's base clock rate and then run through a transition detector. The maximum count rate is one-half of the eTimer's base clock rate when using an external signal. Internal clock sources can be used to clock the counters at the eTimer's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CNTMODE field in the CTRL1 register is cleared when the count terminates.

39.4.2.1 STOP Mode

If the CNTMODE field is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

39.4.2.2 COUNT Mode

If the CNTMODE field is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting the PIPS bit, then the negative edge of the selected external input signal is counted.

See CASCADE-COUNT Mode through VARIABLE-FREQUENCY PWM Mode for additional capabilities of this operating mode.

39.4.2.3 EDGE-COUNT Mode

If the CNTMODE field is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment such as a simple encoder wheel.

39.4.2.4 GATED-COUNT Mode

If the CNTMODE field is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting the SIPS bit, then the counter will count while the selected secondary input is low.

39.4.2.5 QUADRATURE-COUNT Mode

If the CNTMODE field is set to 100, the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signals provides both count and direction information.

The following figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

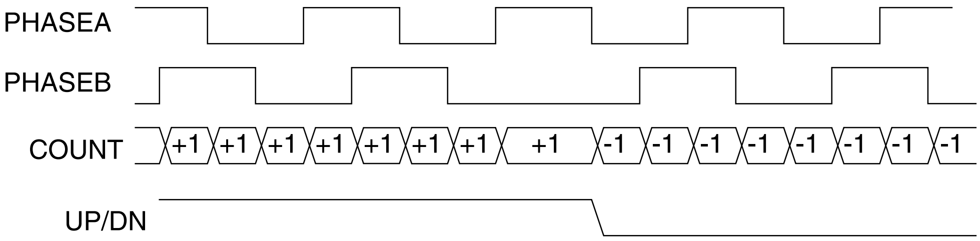

Figure 39-3. Quadrature Incremental Position Encoder

39.4.2.6 SIGNED-COUNT Mode

If the CNTMODE field is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

39.4.2.7 TRIGGERED-COUNT Mode

If the CNTMODE field is set to '110', the counter will begin counting the primary clock source after a positive transition (negative if SIPS = 1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. Subsequent secondary positive input transitions will continue to restart and stop the counting until a compare event occurs.

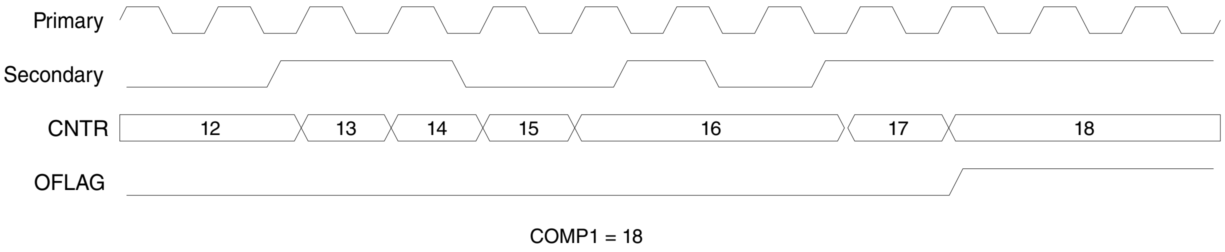

Figure 39-4. Triggered Count Mode (Length=1)

39.4.2.8 ONE-SHOT Mode

If the CNTMODE field is set to '110', and the counter is set to reinitialize at a compare event (LENGTH =1), and the OFLAG OUTMODE is set to '0101' (cleared on init, set on compare), the counter works in a "One-Shot Mode". An external events causes the counter to count, when terminal count is reached, the output is asserted. This "delayed" output can be used to provide timing delays.

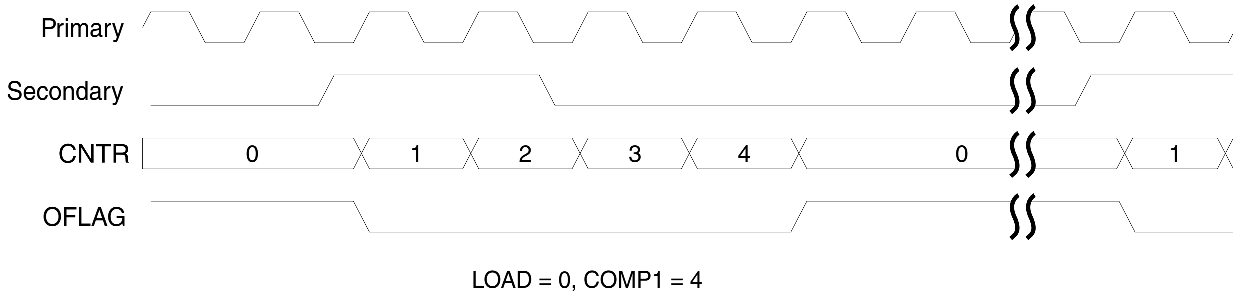

Figure 39-5. One-Shot Mode (Length=1)

39.4.2.9 CASCADE-COUNT Mode

If the CNTMODE field is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This "Cascade" or "Daisy-Chained" mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to two counters may be cascaded to create a 32 bit wide synchronous counter.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective HOLD registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the HOLD registers of the other counters in the chain. The cascaded counter mode is synchronous.

Note

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a "ripple" mode, where higher order counters will transition a clock later than a purely synchronous design.

Note

A channel can be cascaded with any other channel, but you can't cascade more than 2 channels together. You can create separate cascades of pairs of channels. For example, you can cascade channels 0 and 1 and separately cascade channels 6 and 5. You can't cascade channels 0, 1, and 5.

39.4.2.10 PULSE-OUTPUT Mode

If the counter is setup for CNTMODE = 001, and the OFLAG OUTMODE is set to '1111' (gated clock output), and the ONCE bit is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

Note

This does not work if the PRISRC is set to 11000 (IP_bus/1).

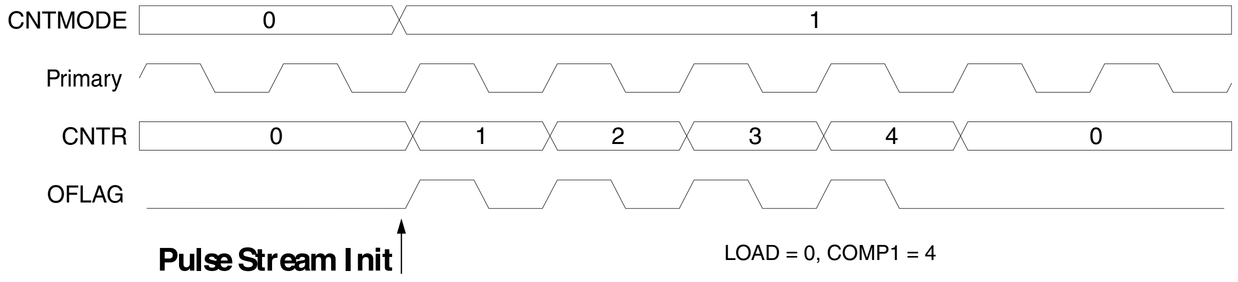

Figure 39-6. Pulse Output Mode

39.4.2.11 FIXED-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count through roll-over (LENGTH = 0), continuous count (ONCE = 0) and the OFLAG OUTMODE is '0111' (set on compare, cleared on counter roll-over) then the counter output yields a Pulse Width Modulated

(PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

39.4.2.12 VARIABLE-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count till compare (LENGTH = 1), continuous count (ONCE = 0) and the OFLAG OUTMMODE is '0100' (toggle OFLAG and alternate compare registers) then the counter output yields a Pulse Width Modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

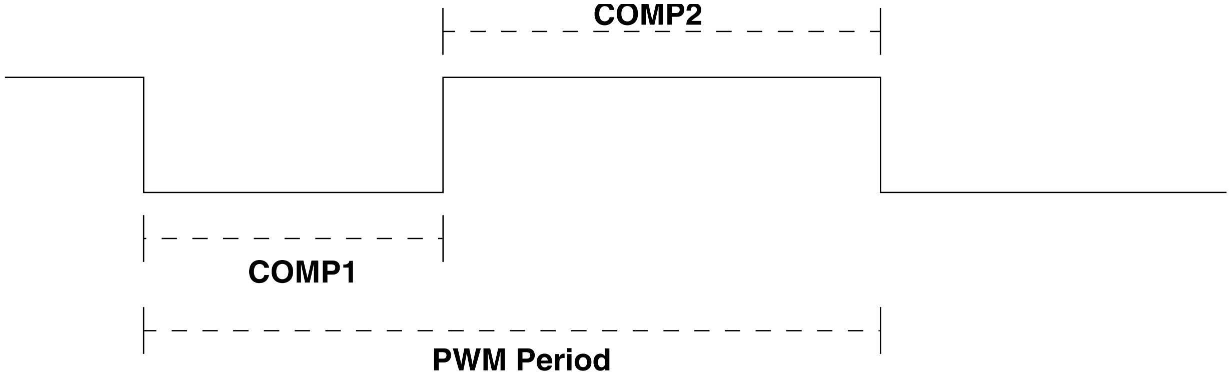

Figure 39-7. Variable PWM Waveform

CLC2=101, load COMP2 when CNTR=COMP2

Figure 39-8. Variable Frequency PWM Mode Timing

39.4.2.13 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability.

The COMP1 register should be set to the desired maximum count value or FFFFh to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If the output mode is set to 0100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time. COMP1 is used when OFLAG=0 and COMP2 is used when OFLAG=1. OFLAG can be forced to a value using CTRL2[FORCE] and CTRL2[VAL].

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFh or 0000h, roll over, then begin counting toward the new value. The check is: CNTR = COMPx, *not* CNTR > COMP1 or CNTR < COMP2.

The use of the CMPLD1 and CMPLD2 registers to preload compare values will help to minimize this problem.

39.4.2.14 Usage of Compare Load Registers

The CMPLD1, CMPLD2 and CCCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. A compare register can be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there is the possibility that the counter may have already counted past the new compare value by the time the compare register is updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are updated in hardware in the same way the counter register is re-initialized to the value stored in the LOAD register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See Figure 39-8.

39.4.2.15 MODULO COUNTING Mode

To create a modulo counter using COMP1 and COMP2 as the counter boundaries (instead of $0000 and $FFFF), set the registers in the following manner. Set CNTMODE to either 100 (quadrature count mode) or 101 (count with direction mode). Use count through roll-over (LENGTH = 0) and continuous count (ONCE = 0). Set COMP1 and CMPLD1 to the upper boundary value. Set COMP2 and CMPLD2 to the lower boundary value. Set CMPMODE = 10 (COMP1 is used when counting up and COMP2 is used when counting down). Set CLC2 = 110 (load CNTR with value of CMPLD2 on COMP1 compare) and CLC1 = 111 (load CNTR with value of CMPLD1 on COMP2 compare).

39.4.2.16 Compare Register and OFLAG Operation

The compare flags and output flag are registered signals and can only change state after the counter reached the compare value. This means that, if the counter is continuously counting, then the compare flag is set on the count after the counter reaches the compare value. When counting is not continuous (such as when using a prescaler or when counting edges on the primary input), the compare flag or OFLAG are not updated until the counter is about to transition to the next count. This means that if the compare value is 4, then the flags will be changed on the same clock edge that transitions the counter from 4 to its next value.

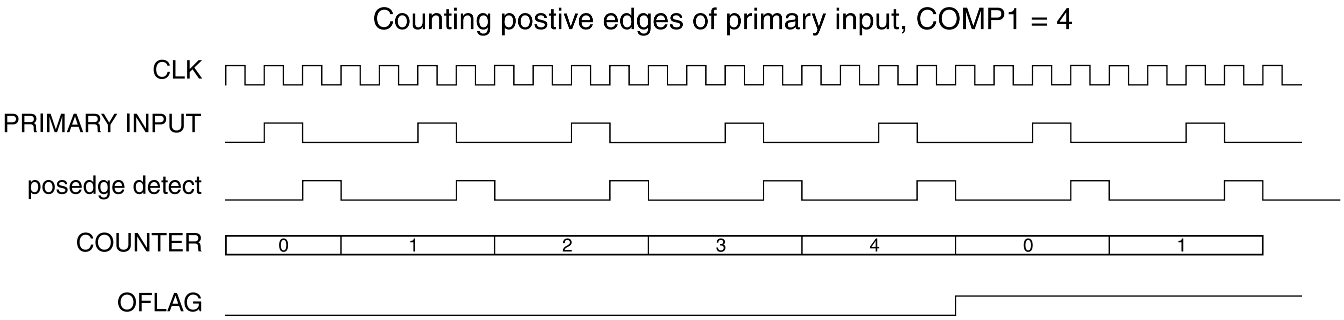

Figure 39-10. OFLAG timing during non-continuous counting

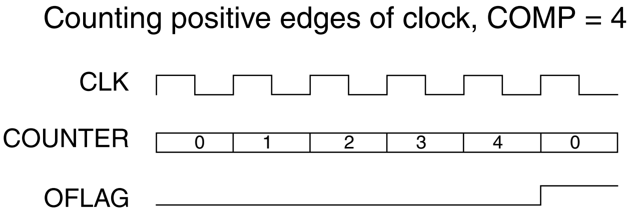

Figure 39-11. OFLAG timing during continuous counting

39.4.3 Other Features

This section describes other features of eTimer.

39.4.3.1 Redundant OFLAG Checking

This mode allows the user to bundle two timer functions generating any pattern to compare their resulting OFLAG behaviors (output signal).

The redundant mode is used to support online checks for reliability and functional safety reasons. Whenever a mismatch between the two adjacent channels occurs, it is reported via an interrupt to the core and the two outputs are put into their inactive states. An error is flagged via the RCF flag.

This feature can be tested by forcing a transition on one of the OFLAGs using the VAL and FORCE bits of the channel.

39.4.3.2 Loopback Checking

This mode is always available in that one channel can generate an OFLAG while another channel uses the first channels OFLAG as its input to be measured and verified to be as expected.

39.4.3.3 Input Capture Mode

Input capture is used to measure pulse width (by capturing the counter value on two successive input edges) or waveform period (by capturing the counter value on two consecutive rising edges or two consecutive falling edges). The Capture Registers store a copy of the counter's value when an input edge (positive, negative, or both) is detected. The type of edge to be captured by each circuit is determined by the CPT1MODE and CPT2MODE bits whose functionality is listed in CPT1MODE. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

39.4.3.4 Master/Slave Mode

Any timer channel can be assigned as a Master (MSTR = 1). A Master's compare signal can be broadcasted to the other channels within the module. The other counters can be configured to reinitialize their counters (COINIT = 1) and/or force their OFLAG output signals (COFRC = 1) to predetermined values when a Master counter compare event occurs.

39.4.3.5 Watchdog Timer

NOTE

> The watchdog timer may not be implemented on each eTimer module instance.

The watchdog timer is used to monitor for a stalled count when channel 0 is in quadrature count mode. When the watchdog is enabled, it loads the time-out value into a down counter. The down counter counts as long as channel 0 is in quadrature decode count mode. If this down counter reaches zero, an interrupt is asserted. The down counter is reloaded to the time-out value each time the counter value from channel 0 changes. If the channel 0 count value is toggling between two values (indicating a possibly stalled encoder), then the down counter is not reloaded.

39.5 Resets

The eTimer module can only be reset by a full system reset. This forces all registers to their reset state and clears the OFLAG signals if they are asserted. The counters will be turned off until the settings in the CTRL registers are changed.

39.6 Clocks

Each timer channel receives its own copy of the peripheral bus clock. This allows for better power management by turning off the clock to unused channels. The watchdog timer (if implemented) has its own version of this clock. Each bit of the ENBL register uses the clock for that corresponding channel. The DREQn registers use the clock for channel, 0 but this clock can be turned off after these registers have been programmed.

39.7 Interrupts

The following can generate interrupts within the eTimer.

- Watchdog timer (if implemented)
- Each channel can generate an interrupt from several sources

The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 39-1. Interrupt summary

Core interrupt	Interrupt flag	Interrupt enable	Name	Description
Channels 0-n	TCF	TCFIE	Compare interrupt	Compare of counter and related compare register
	TCF1	TCF1IE	Compare 1 interrupt	Compare of the counter and COMP1 register
	TCF2	TCF2IE	Compare 2 interrupt	Compare of the counter and COMP2 register
	TOF	TOFIE	Overflow interrupt	Generated on counter roll-over or roll-under
	IELF	IELFIE	Input Low Edge interrupt	Falling edge of the secondary input signal
	IEHF	IEHFIE	Input High Edge interrupt	Rising edge of the secondary input signal
	ICF1	ICF1IE	Input Capture 1 interrupt	Input capture event for CAPT1
	ICF2	ICF2IE	Input Capture 2 interrupt	Input capture event for CAPT2
Watchdog[1]	WDF	WDFIE	Watchdog time-out interrupt	Watchdog has timed out
Redundant Channel Checking	RCF	RCFIE	Redundant Channel Fault interrupt	Miscompare with redundant channel

[1] If applicable. Not all instantiations of eTimer implement a watchdog timer.

39.8 DMA

Each channel can request a DMA read access for each of the capture registers and a DMA write request for each of the compare preload registers. The DREQ registers select amongst these 32 DMA request sources to generate the 4 top level DMA request outputs.

Table 39-2. DMA Summary

DMA Request	DMA Enable	Name	Description
Channels 0-n	ICF1DE	CAPT1 read request	CAPT1 contains a value
	ICF2DE	CAPT2 read request	CAPT2 contains a value
	CMPLD1DE	CMPLD1 write request	CMPLD1 needs an update
	CMPLD2DE	CMPLD2 write request	CMPLD2 needs an update

Chapter 40
Motor Control Pulse Width Modulator Module (FlexPWM)

40.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section contains features, modes of operation, and block diagrams of the FlexPWM.

40.1.1 Overview

The pulse width modulator module (FlexPWM) contains one or more PWM submodules, each capable of controlling a single half-bridge power stage. One or more fault channels may also be included.

This PWM is capable of controlling most motor types: AC induction motors (ACIM), Permanent Magnet AC motors (PMAC), both brushless (BLDC) and brush DC motors (BDC), switched (SRM) and variable reluctance motors (VRM), and stepper motors.

40.1.2 Features

The FlexPWM module provides the following features:

- 16 bits of resolution for center, edge aligned, and asymmetrical PWMs
- PWM outputs capable of operating as complementary pairs or independent channels
- Can accept signed numbers for PWM generation
- Independent control of both edges of each PWM output

- Synchronization to external hardware or other PWM supported
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a "Force Out" event
- PWMX pin can optionally output a third PWM signal from each submodule
- PWMX channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions
- Capture is supported only for X channels not A and B channels
- Enhanced dual edge capture functionality
- The option to supply the source for each complementary PWM signal pair from any of the following:
  - External digital pin
  - Internal timer channel
  - External ADC input, taking into account values set in ADC high and low limit registers

40.1.3 Modes of operation

Care must be exercised when using this module in certain chip operating modes. Some motors (such 3-phase AC motors) require regular software updates for proper operation. Failure to do so could result in destroying the motor or inverter. Because of this, PWM outputs are placed in their inactive states in STOP mode, and optionally under debug mode. PWM outputs are reactivated (assuming they were active to begin with) when these modes are exited.

Table 40-1. Modes when PWM operation is restricted

Mode	Description
STOP	Peripheral and CPU clocks are stopped. PWM outputs are driven inactive.
DEBUG	CPU and peripheral clocks continue to run, but CPU maybe stalled for periods of time. PWM outputs are driven inactive as a function of the DBGEN bit.

40.1.4 Block Diagrams

This section contains block diagrams of the FlexPWM.

40.1.4.1 Module level

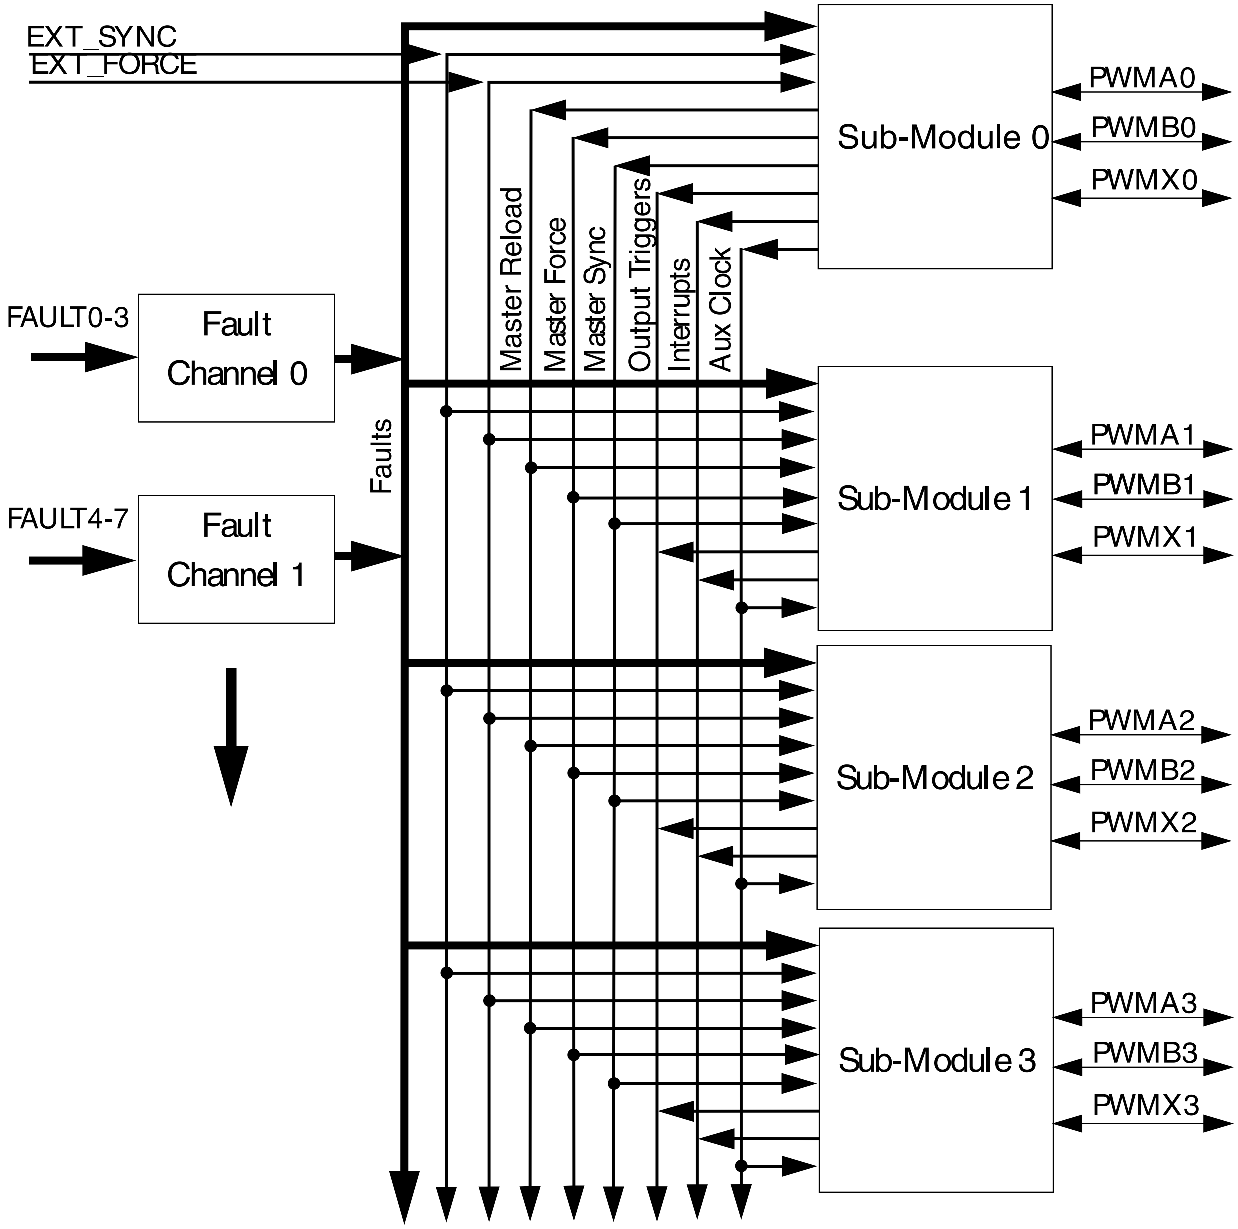

Figure 40-1. PWM block diagram

40.1.4.2 PWM submodule

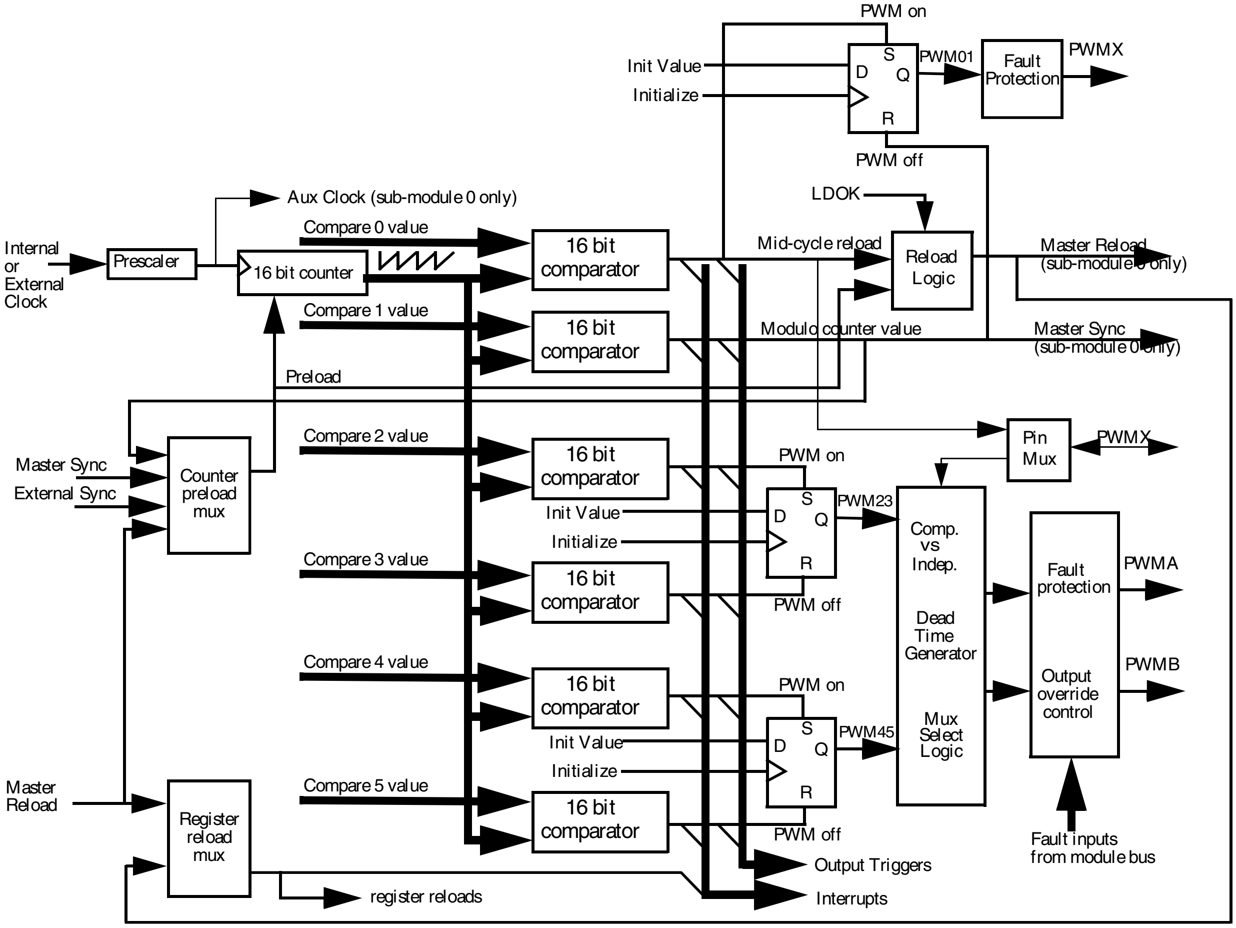

Figure 40-2. PWM submodule block diagram

40.2 External Signal Descriptions

The PWM module has external pins named PWMA[n], PWMB[n], PWMX[n], FAULT[n], EXT_SYNC, EXT_FORCE, EXTA[n], and EXTB[n]. The PWM module also has an on chip input called EXT_CLK and an on-chip output called OUT_TRIG[n].

40.2.1 PWMA[n] and PWMB[n] - External PWM Pair

These pins are the output pins of the PWM channels. They can be independent PWM signals or a complementary pair.

40.2.2 PWMX[n] - Auxiliary PWM signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or they can be used to generate the IPOL bit during deadtime correction.

40.2.3 FAULT[n] - Fault inputs

These are input pins for disabling selected PWM outputs.

40.2.4 EXT_SYNC - External Synchronization Signal

This input signal allows a source external to the PWM to initialize the PWM counter. In this manner the PWM can be synchronized to external circuitry.

40.2.5 EXT_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner the PWM can be synchronized to external circuitry. An example would be to simultaneously switch all of the PWM outputs on a commutation boundary for trapezoidal control of a BLDC motor. The boundary can be established via external logic or an on-chip timer.

40.2.6 EXTA[n] and EXTB[n] - Alternate PWM Control Signals

These pins allow an alternate source to control the PWMA and PWMB outputs although typically, the EXTA input will be used for the generation of a complementary pair. Typical connections include ADC results registers, TMR outputs, GPIO inputs, and comparator outputs.

40.2.7 OUT_TRIG0[n] and OUT_TRIG1[n] - Output Triggers

These outputs allow the PWM submodules to control timing of the ADC conversions. See Submodule n Output Trigger Control Register (FlexPWM_SUB*n*_TCTRL) for a description of how to enable these outputs and how the compare registers match up to the output triggers.

40.2.8 EXT_CLK - External Clock Signal

This on-chip input signal allows an on-chip source external to the PWM (typically a Timer) to control the PWM clocking. In this manner the PWM can be synchronized to the Timer. This signal must be generated synchronously to the PWM's clock since it is not resynchronized in the PWM.

40.2.9 EXT_SWITCH - External Switch Signal

This input signal allows a source external to the PWM to control the PWM generation source within submodule1. This signal only functions on submodule1 and selects the source of the generated PWM signal to be either submodule1 or submodule0.

40.3 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level and the address offset is defined at the module level. There are a set of registers for each PWM submodule, for the configuration logic, and for each Fault channel.

Registers are only accessible using 16- or 32-bit accesses. Byte accesses are not allowed.

Submodule registers are repeated for each PWM submodule. The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is 50h. This is the base address of the PWM module plus an offset based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same offset.

The base address of the configuration registers is equal to the base address of the FlexPWM plus as offset of 140h.

The base address of the fault logic is equal to the base address of the FlexPWM plus an offset of 14Ch.

NOTE

A write access to the read-only Capture Value and Capture Value Cycle registers will result in a bus error.

40.3.1 Submodule n Counter Register (FlexPWM_SUB*n*_CNT)

This read-only register displays the state of the signed 16-bit submodule counter. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 0h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CNT															
Write	▨															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CNT field descriptions

Field	Description
0–15 CNT	Count State of the signed 16-bit submodule counter

40.3.2 Submodule n Initial Count Register (FlexPWM_SUB*n*_INIT)

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of INIT_SEL) or when FORCE is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

NOTE

> The INIT register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. This register cannot be written when LDOK is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 2h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	INIT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_INIT field descriptions

Field	Description
0–15 INIT	Initial count Initial count value for the PWM in PWM clock periods

40.3.3 Submodule n Control 2 Register (FlexPWM_SUB*n*_CTRL2)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 4h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read Write	DBGEN	Reserved	INDEP	PWM23_INIT	PWM45_INIT	PWMX_INIT	INIT_SEL	
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	FRCEN	0	FORCE_SEL			RELOAD_SEL	CLK_SEL	
Write		FORCE						
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CTRL2 field descriptions

Field	Description
0 DBGEN	Debug Enable When set to one, the PWM will continue to run while the chip is in debug mode. If the device enters debug mode and this bit is zero, then the PWM outputs will be disabled until debug mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in debug mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in debug mode. The key point is PWM parameter updates will not occur in debug mode. Any motors requiring such updates should be disabled during debug mode. If in doubt, leave this bit set to zero.
1 Reserved	This field is reserved.
2 INDEP	Independent or Complementary Pair Operation

Table continues on the next page...

FlexPWM_SUBn_CTRL2 field descriptions (continued)

Field	Description
	This bit determines if the PWMA and PWMB channels will be independent PWMs or a complementary PWM pair. 0 PWMA and PWMB form a complementary PWM pair. 1 PWMA and PWMB outputs are independent PWMs.
3 PWM23_INIT	PWM23 Initial Value This read/write bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT, (see PWM Generation), is asserted.
4 PWM45_INIT	PWM45 Initial Value This read/write bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT, (see PWM Generation), is asserted.
5 PWMX_INIT	PWMX Initial Value This read/write bit determines the initial value for PWMX and the value to which it is forced when FORCE_INIT, (see PWM Generation), is asserted.
6–7 INIT_SEL	Initialization Control Select These read/write bits control the source of the INIT signal which goes to the counter. 00 Local sync (PWMX) causes initialization. 01 Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0. 10 Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0. 11 EXT_SYNC causes initialization.
8 FRCEN	Force Initialization Enable This bit allows the FORCE_OUT signal to initialize the counter without regard to the signal selected by INIT_SEL. This is a software controlled initialization. 0 Initialization from a Force Out event is disabled. 1 Initialization from a Force Out event is enabled.
9 FORCE	Force Initialization If the FORCE_SEL bits are set to 000, writing a 1 to this bit results in a Force Out event. This causes the following actions to be taken: • The PWMA and PWMB output pins will assume values based on the SEL23 and SEL45 bits. • If the FRCEN bit is set, the counter value will be initialized with the INIT register value.
10–12 FORCE_SEL	Force Source Select This read/write bit determines the source of the FORCE OUTPUT signal for this submodule. 000 The local force signal, FORCE, from this submodule is used to force updates. 001 The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0. 010 The local reload signal from this submodule is used to force updates without regard to the state of LDOK. 011 The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0. 100 The local sync signal from this submodule is used to force updates.

Table continues on the next page...

FlexPWM_SUB*n*_CTRL2 field descriptions (continued)

Field	Description
	101 The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0. 110 The external force signal, EXT_FORCE, from outside the PWM module causes updates. 111 reserved
13 RELOAD_SEL	Reload Source Select This read/write bit determines the source of the RELOAD signal for this submodule. When this bit is set, the LDOK bit in submodule 0 should be used since the local LDOK bit will be ignored. 0 The local RELOAD signal is used to reload registers. 1 The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it will force the RELOAD signal to logic 0.
14–15 CLK_SEL	Clock Source Select These read/write bits determine the source of the clock signal for this submodule. 00 The peripheral clock is used as the clock for the local prescaler and counter. 01 EXT_CLK is used as the clock for the local prescaler and counter. 10 Submodule 0's clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it will force the clock to logic 0. 11 reserved

40.3.4 Submodule n Control 1 Register (FlexPWM_SUB*n*_CTRL1)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 6h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	LDFQ				HALF	FULL	DT	
Write								
Reset	0	0	0	0	0	1	0	0

Bit	8	9	10	11	12	13	14	15
Read	0	PRSC			PHSSHFT	LDMOD	0	DBLEN
Write								
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CTRL1 field descriptions

Field	Description
0–3 LDFQ	Load Frequency

Table continues on the next page...

FlexPWM_SUB*n*_CTRL1 field descriptions (continued)

Field	Description
	These buffered read/write bits select the PWM load frequency. The PWM reload frequency is at every LDFQ+1 PWM opportunities. Reset clears the LDFQ bits, selecting loading every PWM opportunity. A PWM opportunity is determined by the HALF and FULL bits. **NOTE:** The LDFQx bits take effect when the current load cycle is complete regardless of the state of the LDOK bit. Reading the LDFQx bits reads the buffered values and not necessarily the values currently in effect.
4 HALF	Half Cycle Reload This read/write bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the SUB*n*_VAL0 register and does not have to be half way through the PWM cycle. 0 Half-cycle reloads disabled. 1 Half-cycle reloads enabled.
5 FULL	Full Cycle Reload This read/write bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the SUB*n*_VAL1 register. Either the HALF or FULL bit must be set in order to move the buffered data into the registers used by the PWM generators. If both the HALF and FULL bits are set, then reloads can occur twice per cycle. 0 Full-cycle reloads disabled. 1 Full-cycle reloads enabled.
6–7 DT	Deadtime These read only bits reflect the sampled values of the PWMX input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–11 PRSC	Prescaler These buffered read/write bits select the divide ratio of the PWM clock frequency selected by CLK_SEL. **NOTE:** Reading the PRSCx bits reads the buffered values and not necessarily the values currently in effect. The PRSCx bits take effect at the beginning of the next PWM cycle and only when the load okay bit, LDOK, is set or LDMOD is set. This field cannot be written when LDOK is set. 000 PWM clock frequency = f_{CLK} 001 PWM clock frequency = f_{CLK} / 2 010 PWM clock frequency = f_{CLK} / 4 011 PWM clock frequency = f_{CLK} / 8 100 PWM clock frequency = f_{CLK} / 16 101 PWM clock frequency = f_{CLK} / 32 110 PWM clock frequency = f_{CLK} / 64 111 PWM clock frequency = f_{CLK} / 128
12 PHSSHFT	Phase Shift Mode Enable This read/write bit is only functional in submodule 0. It is used to enable the EXT_SWITCH input to select the source of the generated PWM23/PWM45 signals within submodule 0. If this enable is clear or the EXT_SWITCH signal is 0, then the PWM23/PWM45 signals generated within submodule 0 are used by the force out logic in submodule 0. If this enable is set and the EXT_SWITCH signal is also set, then the PWM23/PWM45 signals from submodule 1 are used by the force out logic in submodule 0.

Table continues on the next page...

FlexPWM_SUB*n*_CTRL1 field descriptions (continued)

Field	Description
	0 Phase shifted mode is disabled. The EXT_SWITCH input is ignored. Normal operation. 1 Phase shifted mode is enabled. The EXT_SWITCH input is used to select generated PWM source for force out logic in submodule 0.
13 LDMOD	Load Mode Select This read/write bit selects the timing of loading the buffered registers for this submodule. 0 Buffered registers of this submodule are loaded and take effect at the next PWM reload if LDOK is set. 1 Buffered registers of this submodule are loaded and take effect immediately upon LDOK being set.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DBLEN	Double Switching Enable This read/write bit enables the double switching PWM behavior. 0 Double switching disabled. 1 Double switching enabled.

40.3.5 Submodule n Value Register 0 (FlexPWM_SUB*n*_VAL0)

The 16-bit signed value in this buffered, read/write register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWMX signal is set and the local sync signal is reset. This register is not byte accessible.

NOTE

> The SUB*n*_VAL0 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL0 cannot be written when LDOK is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 8h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL0 field descriptions

Field	Description
0–15 VAL0	Value 0 Mid-cycle reload point for the PWM in PWM clock periods

40.3.6 Submodule n Value Register 1 (FlexPWM_SUB*n*_VAL1)

The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter will reload itself with the contents of the INIT register and assert the local sync signal while resetting PWMX. This register is not byte accessible.

NOTE

The SUB*n*_VAL1 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL1 cannot be written when LDOK is set. Reading VAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

NOTE

If SUB*n*_VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. The PWMX output will be low for a minimum of one count every cycle after the count reaches VAL1. When the Master Sync signal (only originated by the Local Sync from sub-module 0) is used to control the timer period, the SUB*n*_VAL1 register can be free for other functions such as PWM generation without duty cycle limitation.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Ah offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL1 field descriptions

Field	Description
0–15 VAL1	Value 1 Modulo count value (maximum count) for the submodule counter

40.3.7 Submodule n Value Register 2 (FlexPWM_SUB*n*_VAL2)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM23 high (PWM submodule). This register is not byte accessible.

NOTE

> The SUB*n*_VAL2 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL2 cannot be written when LDOK is set. Reading VAL2 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Ch offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL2															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL2 field descriptions

Field	Description
0–15 VAL2	Value 2 Count value to set PWM23 high

40.3.8 Submodule n Value Register 3 (FlexPWM_SUB*n*_VAL3)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM23 low (PWM submodule). This register is not byte accessible.

NOTE

> The SUB*n*_VAL3 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL3 cannot be written when

LDOK is set. Reading VAL3 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Eh offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–15 VAL3	Value 3 Count value to set PWM23 low

40.3.9 Submodule n Value Register 4 (FlexPWM_SUB*n*_VAL4)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 high (PWM submodule). This register is not byte accessible.

NOTE

The SUB*n*_VAL4 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL4 cannot be written when LDOK is set. Reading VAL4 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 10h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–15 VAL4	Count value to set PWM45 high

40.3.10 Submodule n Value Register 5 (FlexPWM_SUB*n*_VAL5)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 low (PWM submodule). This register is not byte accessible.

NOTE

The SUB*n*_VAL5 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL5 cannot be written when LDOK is set. Reading VAL5 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 12h offset + (80d × i), where i=0d to 3d

Field	Description
	00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.
14–15 PWMXFS	PWMX Fault State These bits determine the fault state for the PWMX output during fault conditions and STOP mode . It may also define the output state during DEBUG modes depending on the settings of DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.

40.3.12 Submodule n Status Register (FlexPWM_SUB*n*_STS)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 1Ah offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	RUF	REF	RF	0				CFX1	CFX0	CMPF					
Write			w1c	w1c					w1c	w1c	w1c					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_STS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 RUF	Registers Updated Flag This read-only flag is set when SUB*n*_INIT, SUB*n*_VAL*x*, or SUB*n*_CTRL*0x*[PRSC] has been written resulting in non-coherent data in the set of double-buffered registers. Clear RUF by a proper reload sequence consisting of a reload signal while LDOK = 1. Reset clears RUF. 0 No register update has occurred since last reload. 1 At least one of the double buffered registers has been updated since the last reload.
2 REF	Reload Error Flag This read/write flag is set when a reload cycle occurs while LDOK is 0 and the double buffered registers are in a non-coherent state (RUF = 1). Clear REF by writing a logic one to the REF bit. Reset clears REF. 0 No reload error occurred. 1 Reload signal occurred with non-coherent data and LDOK = 0.

40.3.14 Submodule n DMA Enable Register (FlexPWM_SUB*n*_DMAEN)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 1Eh offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	0						VALDE	FAND
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	CAPTDE		Reserved				CX1DE	CX0DE
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_DMAEN field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 VALDE	Value Registers DMA Enable This read/write bit enables DMA write requests for the SUB*n*_VAL*x* registers when RF is set. Reset clears VALDE. 0 DMA write requests disabled 1 DMA write requests for the SUB*n*_VAL*x* registers enabled
7 FAND	FIFO Watermark AND Control This read/write bit works in conjunction with the CAPTDE field when it is set to watermark mode (CAPTDE = 01). While the CAxDE, CBxDE, and CXxDE bits determine which FIFO watermarks the DMA read request is sensitive to, this bit determines if the selected watermarks are AND'ed together or OR'ed together in order to create the request.

Table continues on the next page...

FlexPWM_SUB*n*_DMAEN field descriptions (continued)

Field	Description
	0 Selected FIFO watermarks are OR'ed together. 1 Selected FIFO watermarks are AND'ed together.
8–9 CAPTDE	Capture DMA Enable Source Select These read/write bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits. 00 Read DMA requests disabled. 01 Exceeding a FIFO watermark sets the DMA read request. This requires at least 1 of the CA1DE, CA0DE, CB1DE, CB0DE, CX1DE, or CX0DE bits to also be set in order to determine which watermark(s) the DMA request is sensitive to. 10 A local sync (VAL1 matches counter) sets the read DMA request. 11 A local reload (RF being set) sets the read DMA request.
10–13 Reserved	This field is reserved.
14 CX1DE	Capture X1 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture X1 FIFO data when CFX1 is set. Reset clears CX1DE. Do not set both this bit and the CX1IE bit.
15 CX0DE	Capture X0 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture X0 FIFO data when CFX0 is set. Reset clears CX0DE. Do not set both this bit and the CX0IE bit.

40.3.15 Submodule n Output Trigger Control Register (FlexPWM_SUB*n*_TCTRL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 20h offset + (80d × i), where i=0d to 3d

40.3.17 Submodule n Deadtime Count Register 0 (FlexPWM_SUB*n*_DTCNT0)

Deadtime operation is only applicable to complementary channel operation. The 11-bit value written to this register is in terms of peripheral clock cycles regardless of the setting of PRSC and/or CLK_SEL. Reset sets the deadtime count register to a default value of 0x07FF, selecting a deadtime of 2047 clock cycles. This register is not byte accessible.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 24h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					DTCNT0										
Write																
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

FlexPWM_SUB*n*_DTCNT0 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 DTCNT0	Controls the deadtime during 0 to 1 transitions of the PWMA output (assuming normal polarity) in terms of clock cycles regardless of the setting of PRSC and/or CLK_SEL

40.3.18 Submodule n Deadtime Count Register 1 (FlexPWM_SUB*n*_DTCNT1)

Deadtime operation is only applicable to complementary channel operation. The 11-bit value written to this register is in terms of peripheral clock cycles regardless of the setting of PRSC and/or CLK_SEL. Reset sets the deadtime count register to a default value of 0x07FF, selecting a deadtime of 2047 clock cycles. This register is not byte accessible.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 26h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					DTCNT1										
Write																
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

FlexPWM_SUB*n*_DTCNT1 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 DTCNT1	Controls the deadtime during 0 to 1 transitions of the complementary PWMB output, in terms of clock cycles regardless of the setting of PRSC and/or CLK_SEL

40.3.19 Submodule n Capture Control X Register (FlexPWM_SUB*n*_CAPTCTRLX)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 30h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	CX1CNT			CX0CNT			CFXWM	
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	EDGCNTX_EN	INPSELX	EDGX1		EDGX0		ONESHOTX	ARMX
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CAPTCTRLX field descriptions

Field	Description
0–2 CX1CNT	Capture X1 FIFO Word Count This field reflects the number of words in the Capture X1 FIFO.
3–5 CX0CNT	Capture X0 FIFO Word Count This field reflects the number of words in the Capture X0 FIFO.
6–7 CFXWM	Capture X FIFOs Watermark This field represents the watermark level for capture X FIFOs. The capture flags, CFX1 and CFX0, won't be set until the word count of the corresponding FIFO is greater than this watermark level.
8 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWMX input signal. 0 Edge counter disabled and held in reset. 1 Edge counter enabled.
9 INPSELX	Input Select X This bit selects between the raw PWMX input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. **NOTE:** When INPSELX = 1, the internal edge counter is enabled and the rising and/or falling edges specified by the EDGX0 and EDGX1 fields are ignored. The software must still place a value other than 00 in either or both of the EDGX0 and/or EDGX1 fields in order to enable one or both of the capture registers. 0 Raw PWMX input signal selected as source. 1 Output of edge counter/compare selected as source.

Table continues on the next page...

FlexPWM_SUB*n*_CAPTCTRLX field descriptions (continued)

Field	Description
10–11 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00 Disabled. 01 Capture falling edges. 10 Capture rising edges. 11 Capture any edge.
12–13 EDGX0	Edge X 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00 Disabled. 01 Capture falling edges. 10 Capture rising edges. 11 Capture any edge.
14 ONESHOTX	One Shot Mode Aux This bit selects between free running and one shot mode for the input capture circuitry. 0 Free running mode is selected If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1 One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and the ARMX bit is cleared. No further captures will be performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARMX bit is then cleared.
15 ARMX	Arm X Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s). 0 Input capture operation is disabled. 1 Input capture operation as specified by the EDGX bits is enabled.

40.3.20 Submodule n Capture Compare X Register (FlexPWM_SUB*n*_CAPTCMPX)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 32h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	EDGCNTX								EDGCMPX							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CAPTCMPX field descriptions

Field	Description
0–7 EDGCNTX	Edge Counter X This read only field contains the edge counter value for the PWMX input capture circuitry.
8–15 EDGCMPX	Edge Compare X This read/write field is the compare value associated with the edge counter for the PWMX input capture circuitry.

40.3.21 Submodule n Capture Value 0 Register (FlexPWM_SUB*n*_CVAL0)

This read only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by the EDGX0 bits. This is actually a 4-deep FIFO and not a single register. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 34h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CAPTVAL0															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL0 field descriptions

Field	Description
0–15 CAPTVAL0	Value captured from the submodule counter

40.3.22 Submodule n Capture Value 0 Cycle Register (FlexPWM_SUB*n*_CVAL0CYC)

This read only register stores the cycle number corresponding to the value captured in CVAL0. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. This is actually a 4 deep FIFO and not a single register.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 36h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0													CVAL0CYC		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL0CYC field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 CVAL0CYC	CVAL0 Cycle Cycle number corresponding to the value captured in CVAL0

40.3.23 Submodule n Capture Value 1 Register (FlexPWM_SUB*n*_CVAL1)

This read only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by the EDGX1 bits. This is actually a 4 deep FIFO and not a single register. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 38h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CAPTVAL1															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL1 field descriptions

Field	Description
0–15 CAPTVAL1	Value captured from the submodule counter

40.3.24 Submodule n Capture Value 1 Cycle Register (FlexPWM_SUB*n*_CVAL1CYC)

This read only register stores the cycle number corresponding to the value captured in CVAL1. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. This is actually a 4 deep FIFO and not a single register.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 3Ah offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0													CVAL1CYC		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL1CYC field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 CVAL1CYC	CVAL1 Cycle Cycle number corresponding to the value captured in CVAL1

40.3.25 Output Enable Register (FlexPWM_OUTEN)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 140h offset = 140h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0				PWMA_EN				PWMB_EN				PWMX_EN			
Write

1 PWM generator enabled</td></tr>
<tr><td>8–11
CLDOK</td><td>Clear Load Okay

This write only bit is used to clear the LDOK bit. Write a 1 to this location to clear the corresponding LDOK. If a reload occurs with LDOK set at the same time that CLDOK is written, then the reload will not be performed and LDOK will be cleared. This bit is self clearing and always reads as a 0.

<table>
<tr><th>CLDOK bit</th><th>PWM submodule</th></tr>
<tr><td>0</td><td>0</td></tr>
<tr><td>1</td><td>1</td></tr>
<tr><td>2</td><td>2</td></tr>
<tr><td>3</td><td>3</td></tr>
</table>
</td></tr>
<tr><td>12–15
LDOK</td><td>Load Okay

This field loads the PRSC bits of SUB*n*_CTRL1, SUB*n*_INIT, and SUB*n*_VAL*x* registers into a set of buffers in each submodule. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if LDMOD is clear or immediately if LDMOD is set. Set LDOK by reading it when it is logic zero and then writing a logic one to it. SUB*n*_VAL*x*, SUB*n*_INIT, and SUB*n*_CTRL*x*[PRSC] cannot be written while LDOK is set. LDOK is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic 1 to CLDOK. This bit cannot be written with a zero. LDOK can be set in DMA mode when the DMA indicates that it has completed the update of all SUB*n*_INIT, SUB*n*_VAL*x*, or SUB*n*_CTRL*x*[PRSC]> registers. Reset clears LDOK.

40.3.32 Fault Filter Register (FlexPWM_FFILT)

The settings in this register are shared among each of the fault input filters.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 150h offset = 150h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	GSTR	0				FILT_CNT			FILT_PER							
Write		▨														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_FFILT field descriptions

Field	Description
0 GSTR	Fault Glitch Stretch Enable This bit is used to enable the fault glitch stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 peripheral clock cycles wide. In some cases a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags. 0 Fault input glitch stretching is disabled. 1 Input fault signals will be stretched to at least 2 peripheral clock cycles.
1–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 FILT_CNT	Fault Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in Input Filter Considerations .
8–15 FILT_PER	Fault Filter Period These bits represent the sampling period (in peripheral clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in Input Filter Considerations .

40.3.33 Input Filter Considerations

The FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.

The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT+4) x FILT_PER x peripheral clock period). Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This is to ensure rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set the FFLAG and FFPIN bits of the FSTS register.

40.4 Functional Description

This section describes the functionality of the FlexPWM.

40.4.1 PWM Capabilities

This section describes some capabilities of the PWM module.

40.4.1.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in following figure.

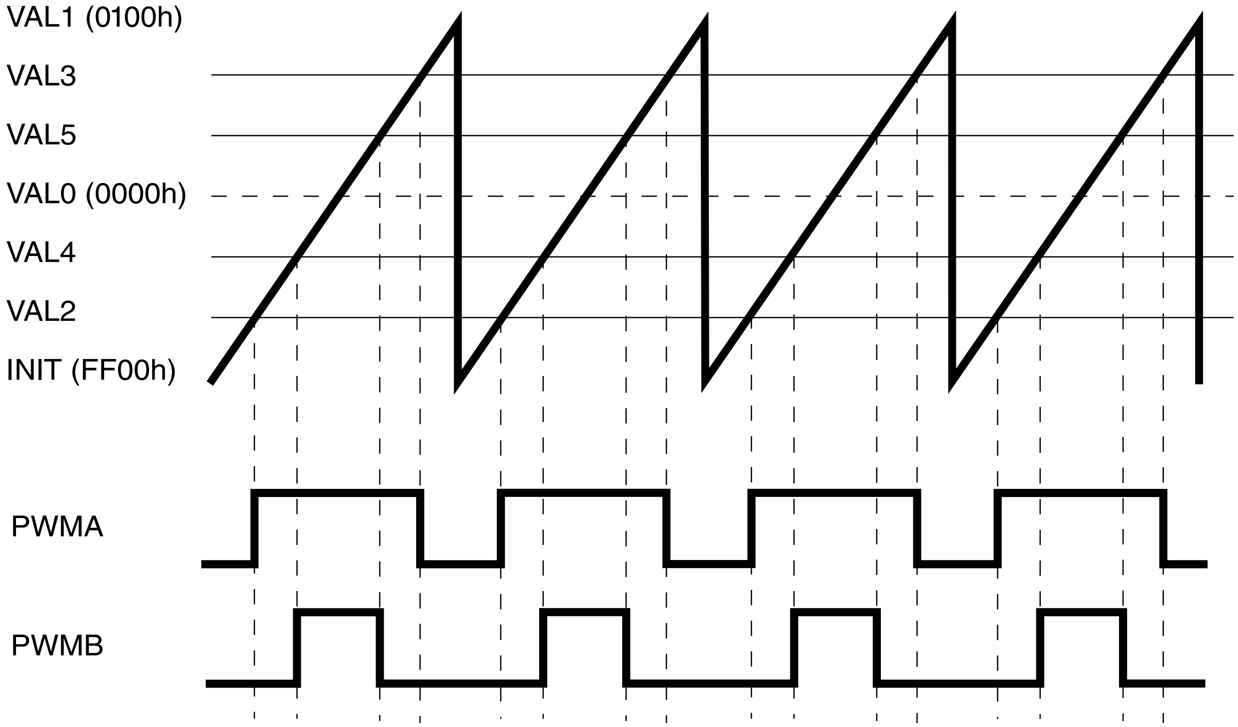

Figure 40-3. Center Aligned Example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

The figure above also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

40.4.1.2 Edge Aligned PWMs

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as illustrated in the following figure. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

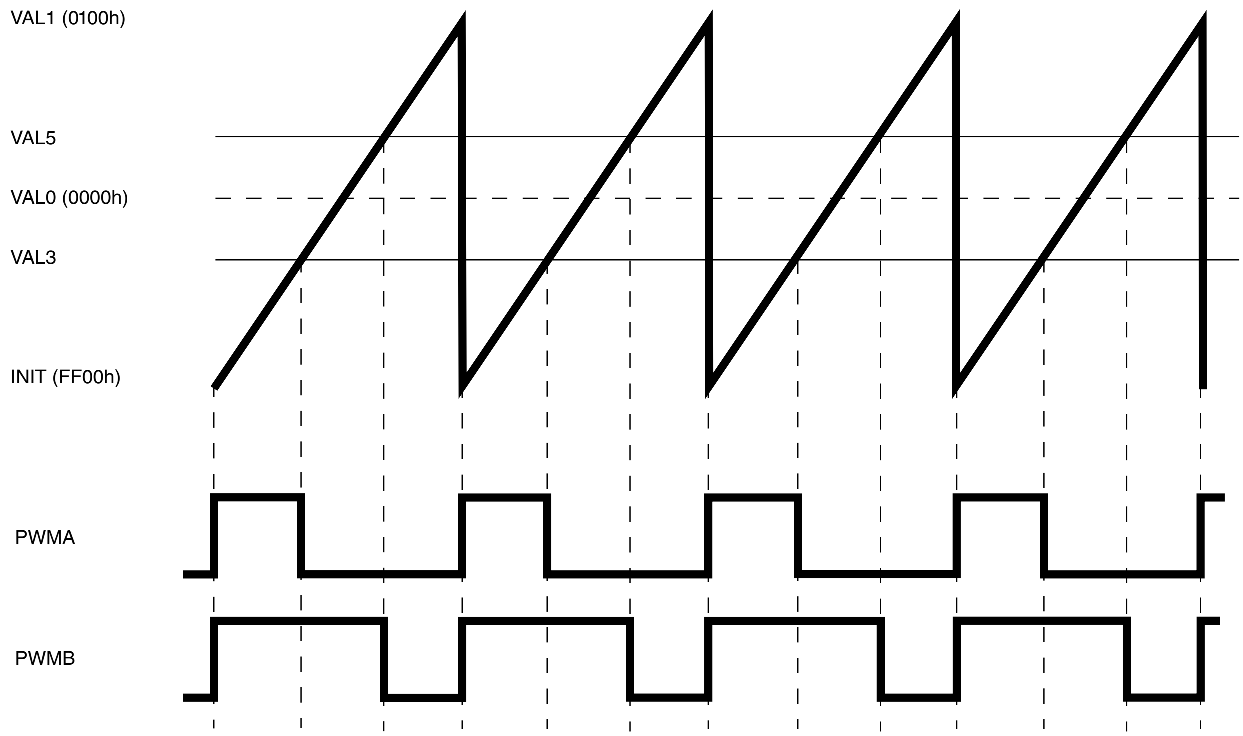

Figure 40-4. Edge Aligned Example (INIT=VAL2=VAL4)

With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn off edge value and the motor voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

40.4.1.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases ARE applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as illustrated in the following figure. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

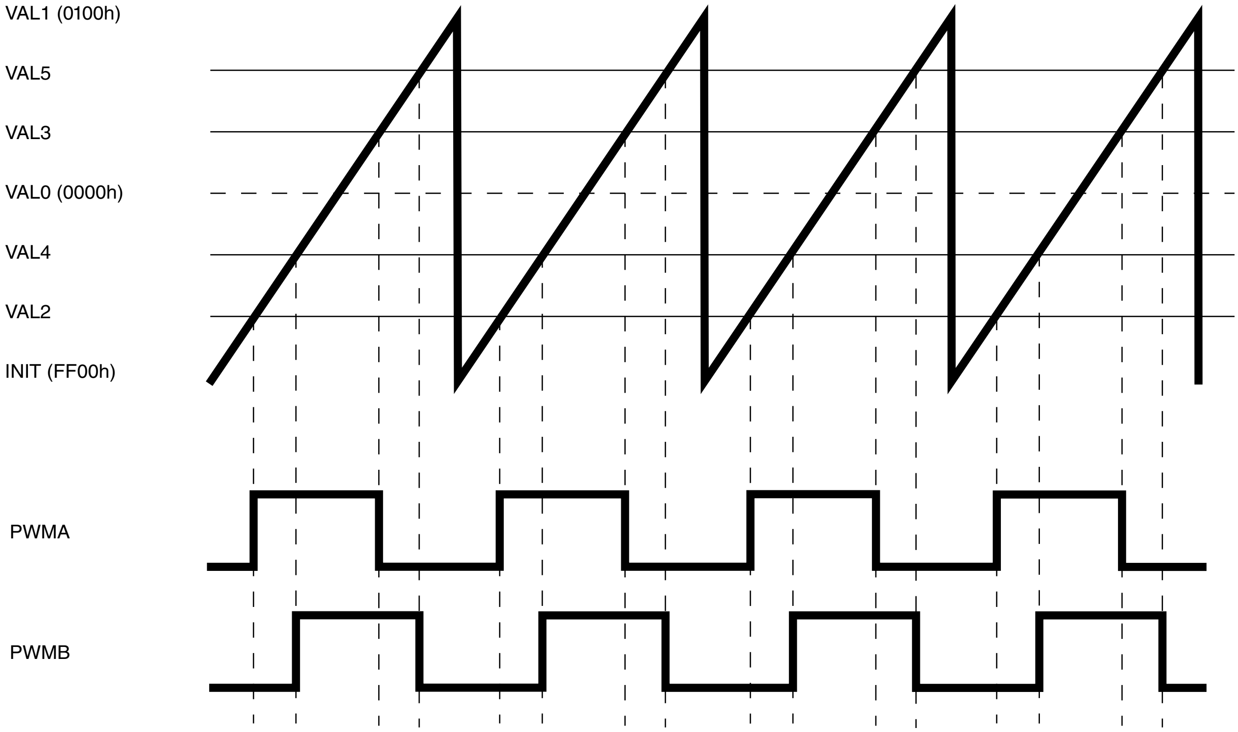

Figure 40-5. Phase Shifted Outputs Example

An additional benefit of phase shifted PWMs can be seen in the following figure. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

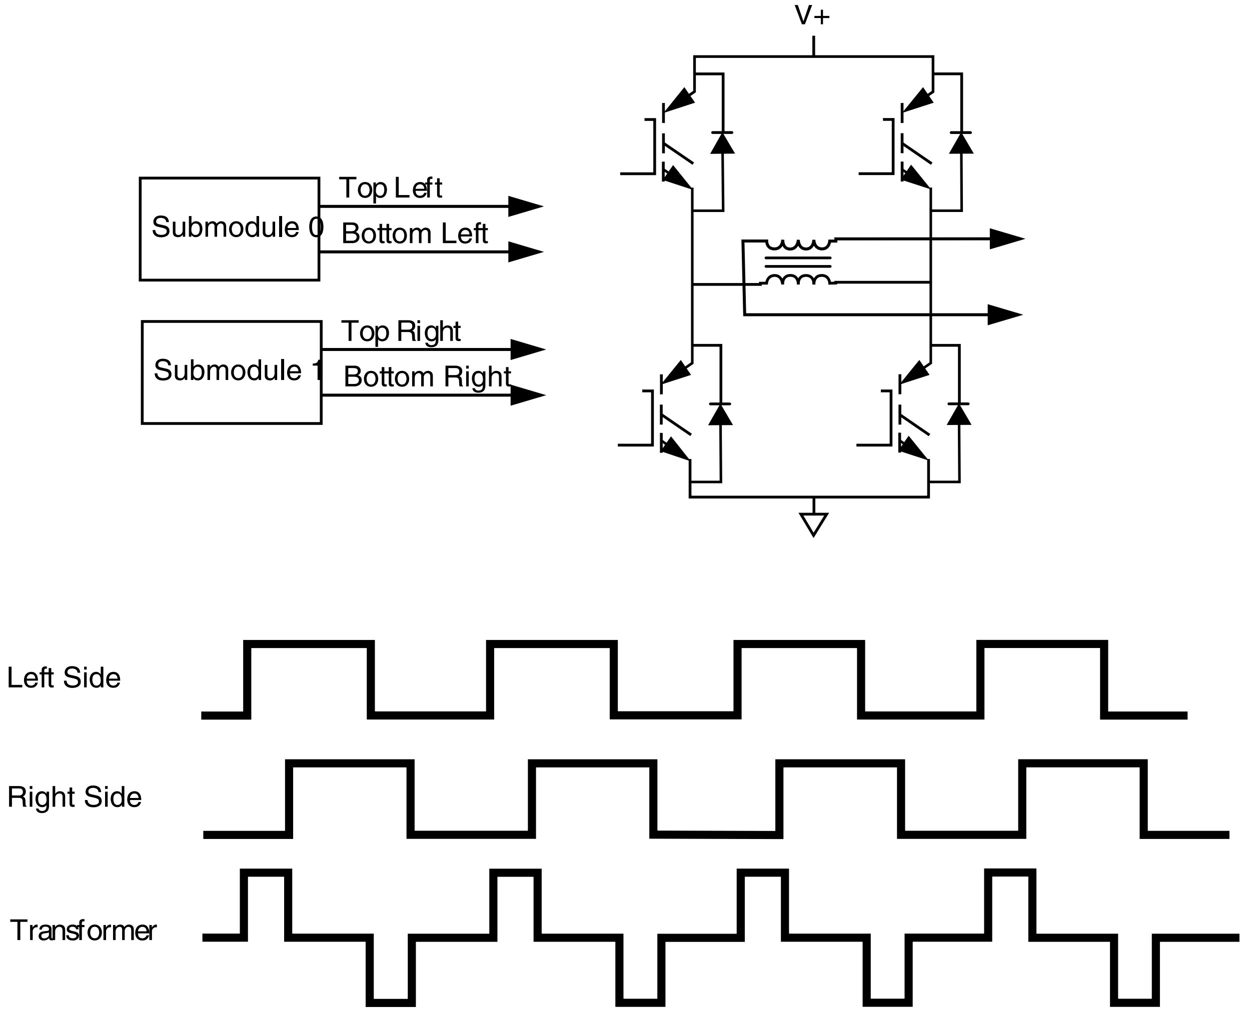

Figure 40-6. Phase Shifted PWMs Applied to a Transformer Primary

40.4.1.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method support two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWMA in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (see Figure 40-17) as shown in the following figure. The DBLPWM signal can be run through the deadtime insertion logic.

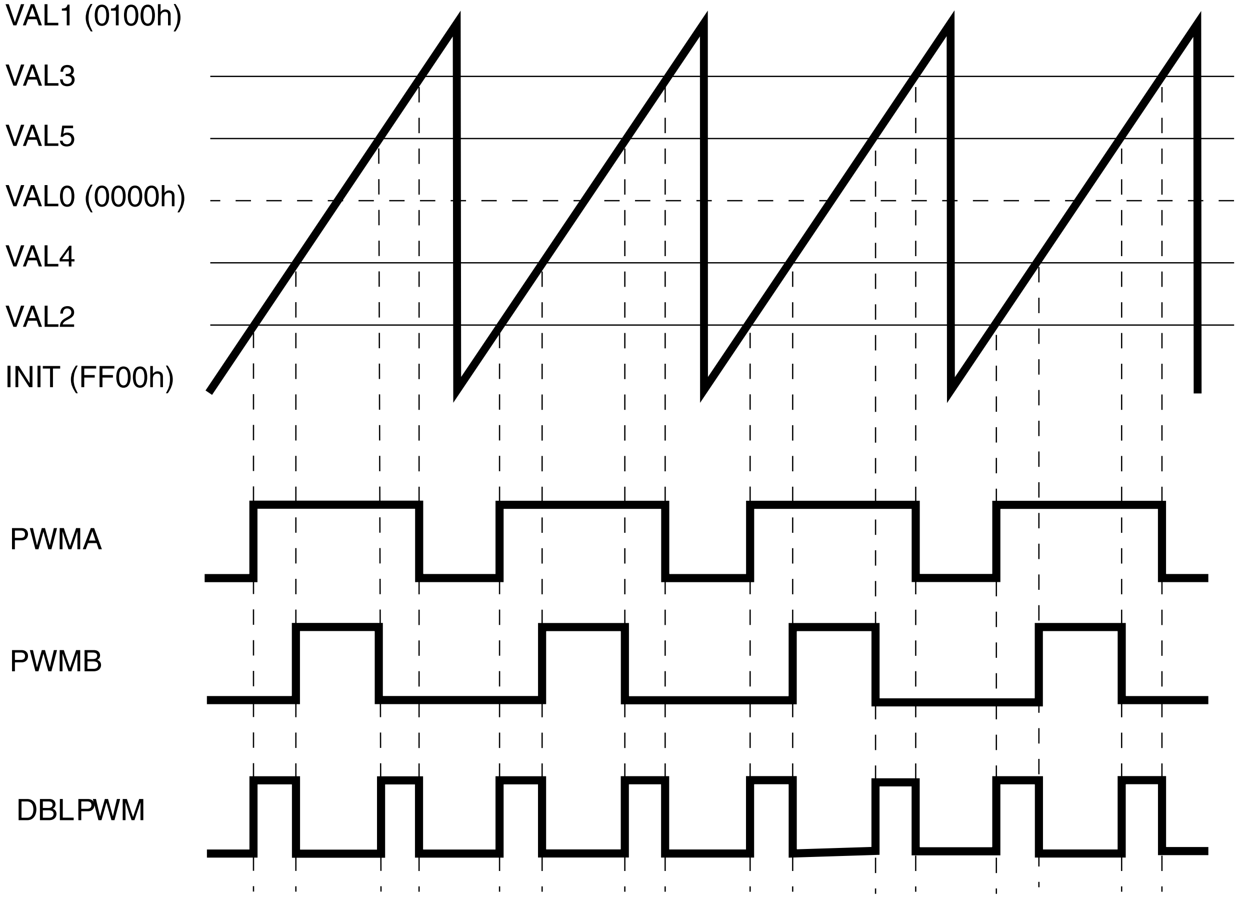

Figure 40-7. Double Switching Output Example

40.4.1.5 ADC Triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. the following figure shows how this is accomplished. When specifying complimentary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators are free to perform other functions. In this example, the software doesn't have to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

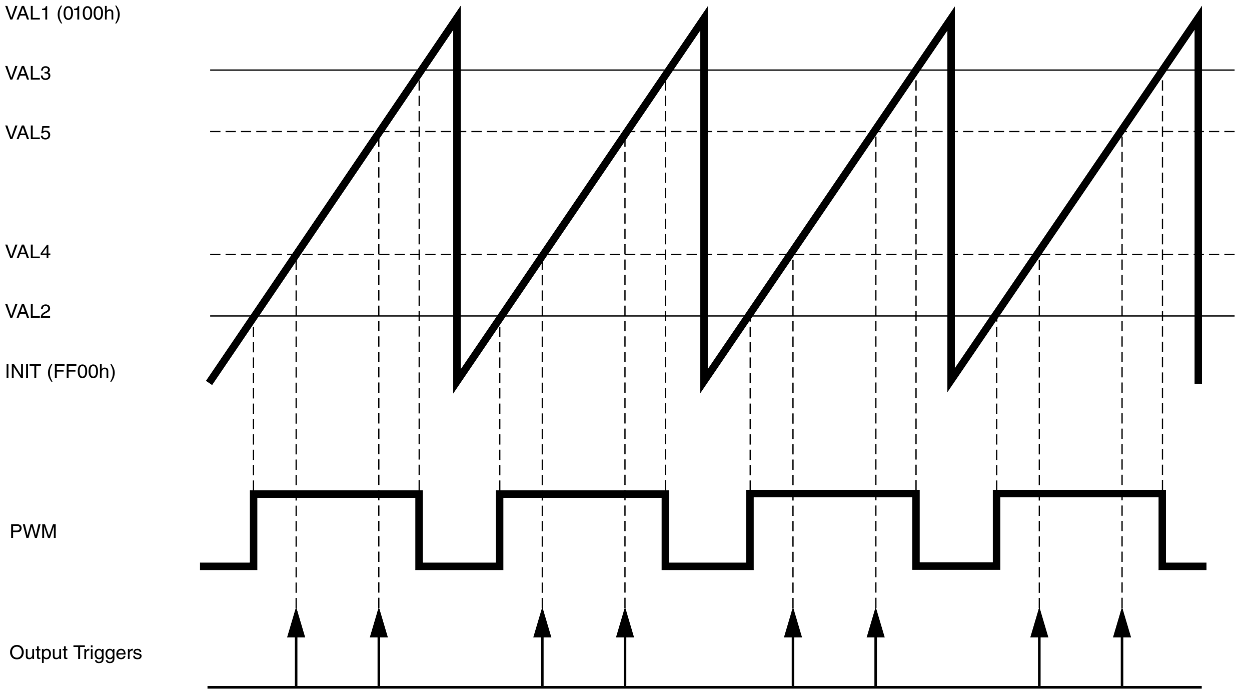

Figure 40-8. Multiple Output Trigger Generation in Hardware

Since each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. The following figure shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In this figure, ALL submodule comparators are shown being used for ADC trigger generation.

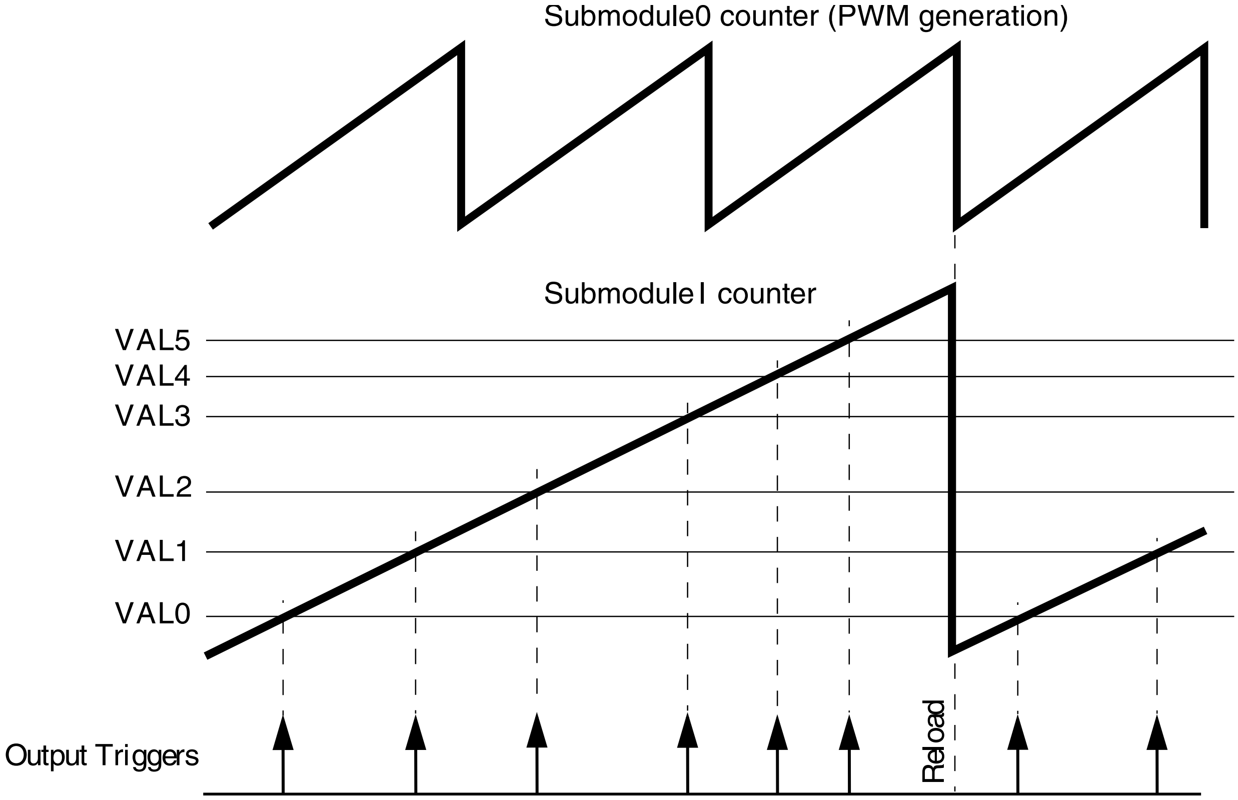

Figure 40-9. Multiple Output Triggers Over Several PWM Cycles

40.4.1.6 Enhanced Capture Capabilities (E-Capture)

When a PWMX pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

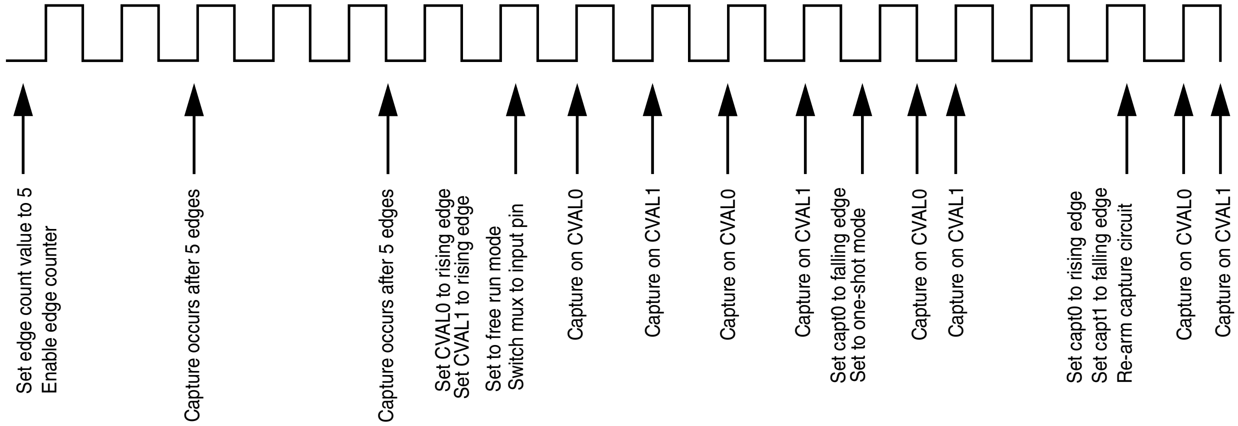

Figure 40-10. Capture Capabilities of the E-Capture Circuit

When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (e.g, PWMX) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. As an example, consider the following figure. In this application the output of a PWM power stage is connected to the PWMX pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVAL0 register value from the CVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays.

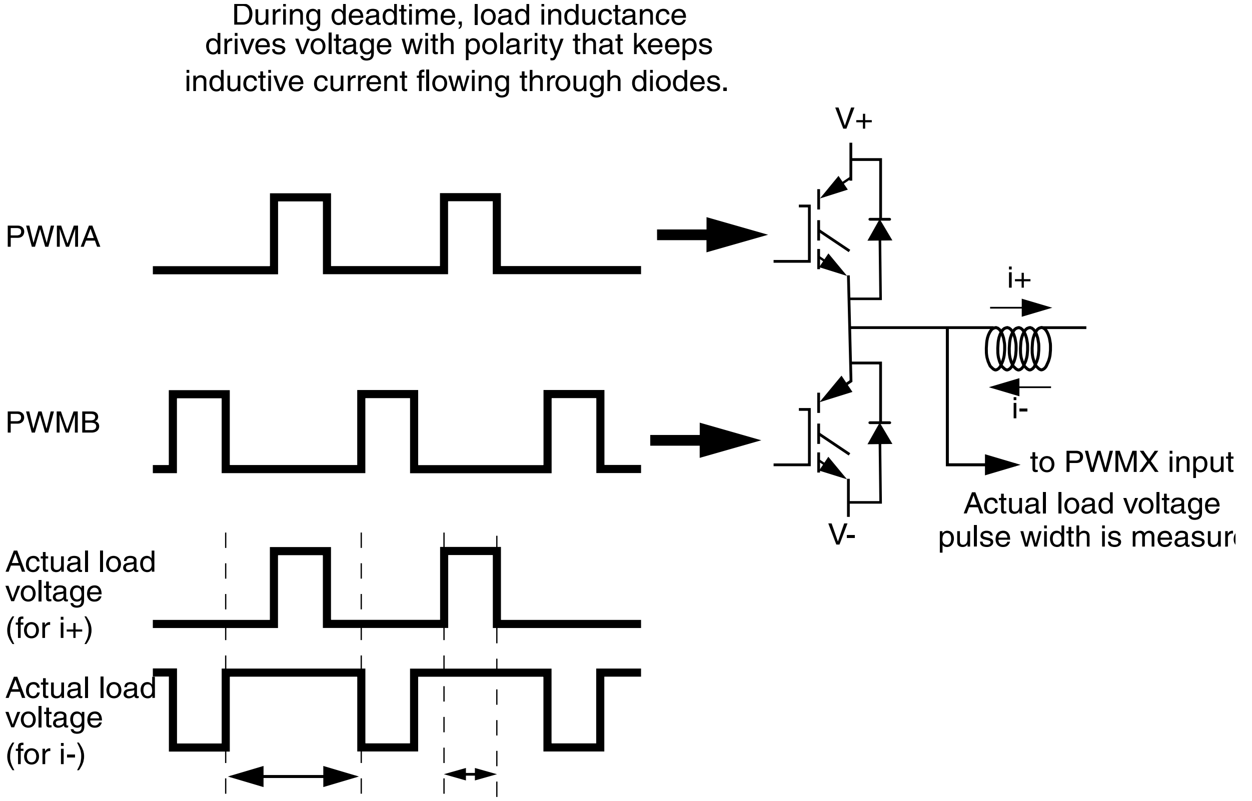

Figure 40-11. Output Pulse Width Measurement Possible with the E-Capture Circuit

40.4.1.7 Synchronous Switching of Multiple Outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature can be extremely useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all submodule outputs, but they occur IMMEDIATELY after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event using the SWCOUT and DTSRCSEL registers. This selection lays dormant until the FORCE_OUT signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

The following figure shows a popular application that can benefit from this feature. On a brushless DC motor it is desirable on many cases to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of the following figure are a simplistic representation of these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

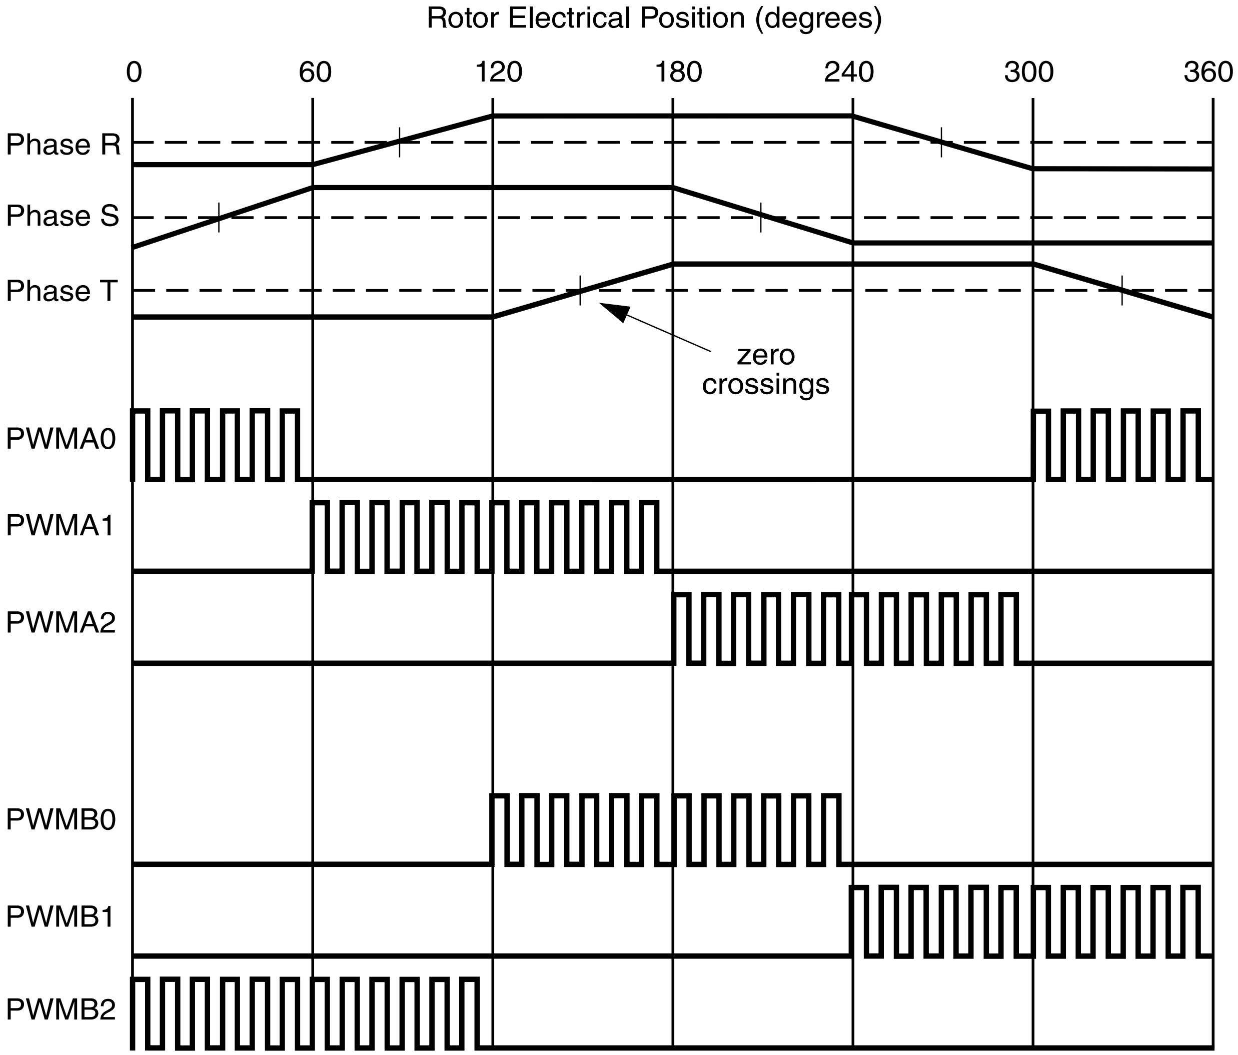

Figure 40-12. Sensorless BLDC Commutation Using the Force Out Function

40.4.1.8 Phase shifted full bridge for DC/DC converters

Use CTRL1[PHSSHFT] to allow the EXT_SWITCH input to control the output of PWMA0/PWMB0. The EXT_SWITCH input switches the source of the submodule0 output from the SUB0_VAL*x* registers to the SUB1_VAL*x* registers. This muxing can be seen in Figure 40-16.

40.4.2 Functional Details

This section describes the implementation of various features of the PWM in greater detail.

40.4.2.1 PWM Clocking

The following figure shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the peripheral clock, EXT_CLK, and AUX_CLK. The EXT_CLK is generated by an on-chip resource such as a Timer module and goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8 bit prescaler and RUN bit from submodule0 can control all of the submodules. When AUX_CLK is selected as the source for the submodule clock, the RUN bit from submodule0 is used instead of the local RUN bit from this submodule.

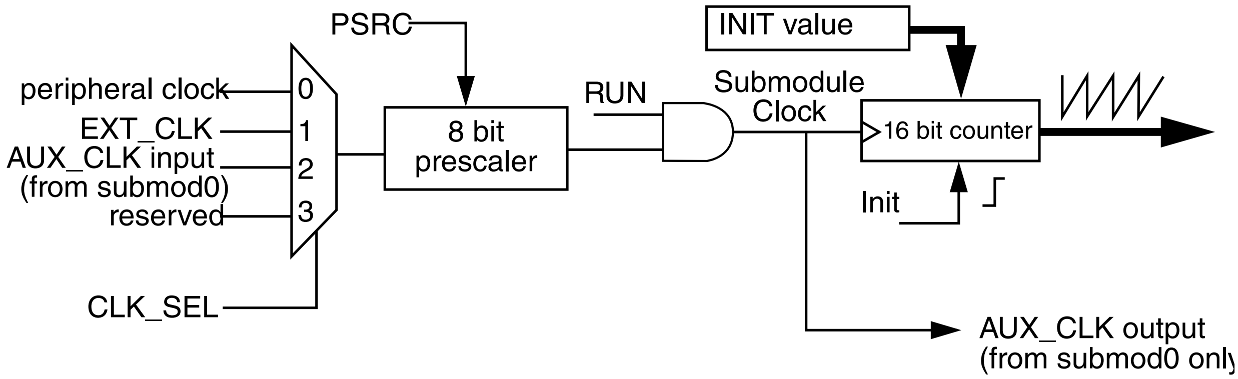

Figure 40-13. Clocking Block Diagram for Each PWM Submodule

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the peripheral clock frequency by 1-128. The prescaler bits, PRSC, in the control register (CTRL1), select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until the LDOK bit is set and a new PWM reload cycle begins or LDMOD is set.

40.4.2.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using the LDFQ bits and the FULL bit. A half cycle reload option is also supported (HALF) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the SUB*n*VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As illustrated in the following figure, the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

Figure 40-14. Register Reload Logic

40.4.2.3 Counter Synchronization

Referring to the following figure, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.

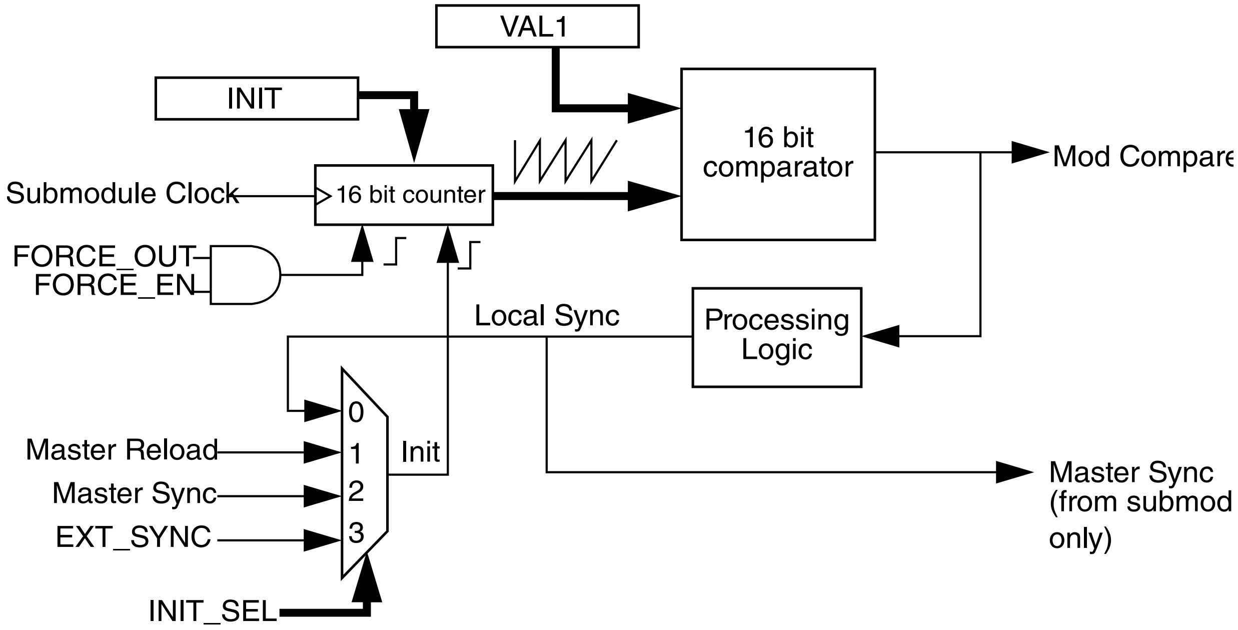

Figure 40-15. Submodule Timer Synchronization

The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0. The SUB*n*_VAL1 register and associated comparator of the other submodules can then be freed up for other functions such as PWM generation, input captures, output compares, or output triggers.

The EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that the FORCE_EN bit is set. As indicated by the figure above, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal. The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event with respect to the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result will be an oscillation caused by the beating between the PWM frequency and the commutation frequency.

40.4.2.4 PWM Generation

The following figure illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated SUB*n*_VAL*x* registers are utilized for each PWM output signal. One comparator and VALx register is used to control the turn on edge while a second comparator and SUB*n*_VAL*x* register control the turn off edge.

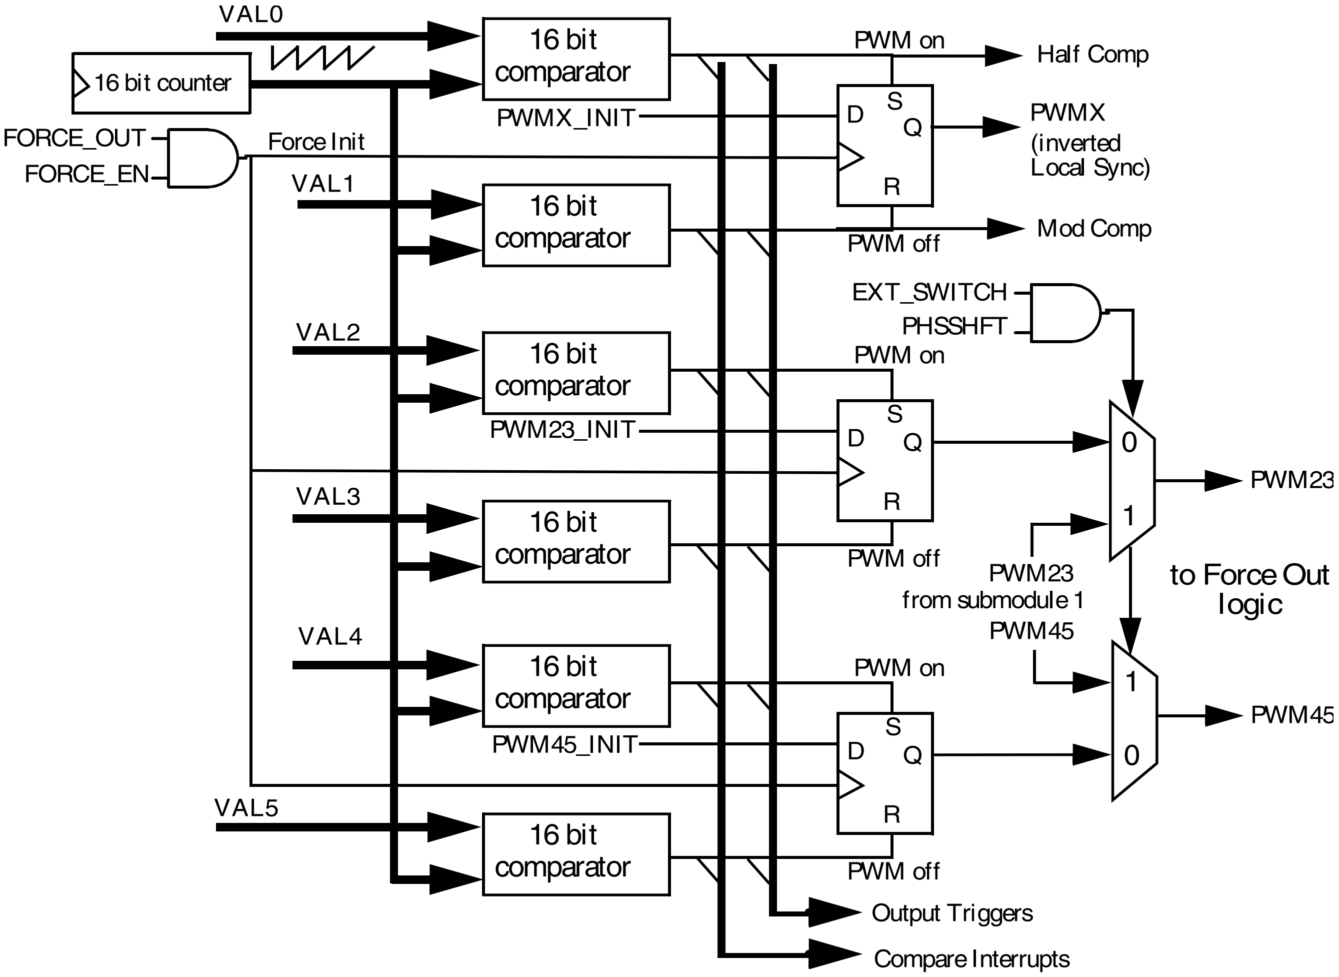

Figure 40-16. PWM Generation Hardware

The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a rising edge of the Local Sync signal, comparator 1 generates a falling edge. Comparator 1 is also hardwired to the reload logic to generate the half cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the SUB*n*_VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the SUB*n*_VAL1 and SUB*n*_VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Sync signal effectively turning it into an auxiliary PWM signal (PWMX) assuming that the PWMX pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating 3 PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The muxes for PWM23 and PWM45, shown in the figure above, are only in submodule0.

If the comparators assert both the set and reset of the flip-flop at the same time, then the flop output goes to 0.

40.4.2.5 Output Compare Capabilities

By using the SUB*n*_VAL*x* registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

Referring again to Figure 40-16, an output compare is initiated by programming a SUB*n*_VAL*x* register for a timer compare which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWMA signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the SUB*n*_VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWMA signal that sets it low, the SUB*n*_VAL3 register is programmed with the appropriate count value and the SUB*n*_VAL2 register is programmed with a value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

40.4.2.6 Force Out Logic

For each submodule software can select between seven signal sources for the FORCE_OUT signal: the local FORCE bit, the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, or the EXT_FORCE signal from on or off chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master signals or EXT_FORCE signal should be selected.

The following figure illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the EXTA or EXTB alternate external control signals. The selection can be determined ahead of time and, when a FORCE_OUT event occurs, these values are presented to the signal selection mux which immediately switches the requested signal to the output of the mux for further processing downstream.

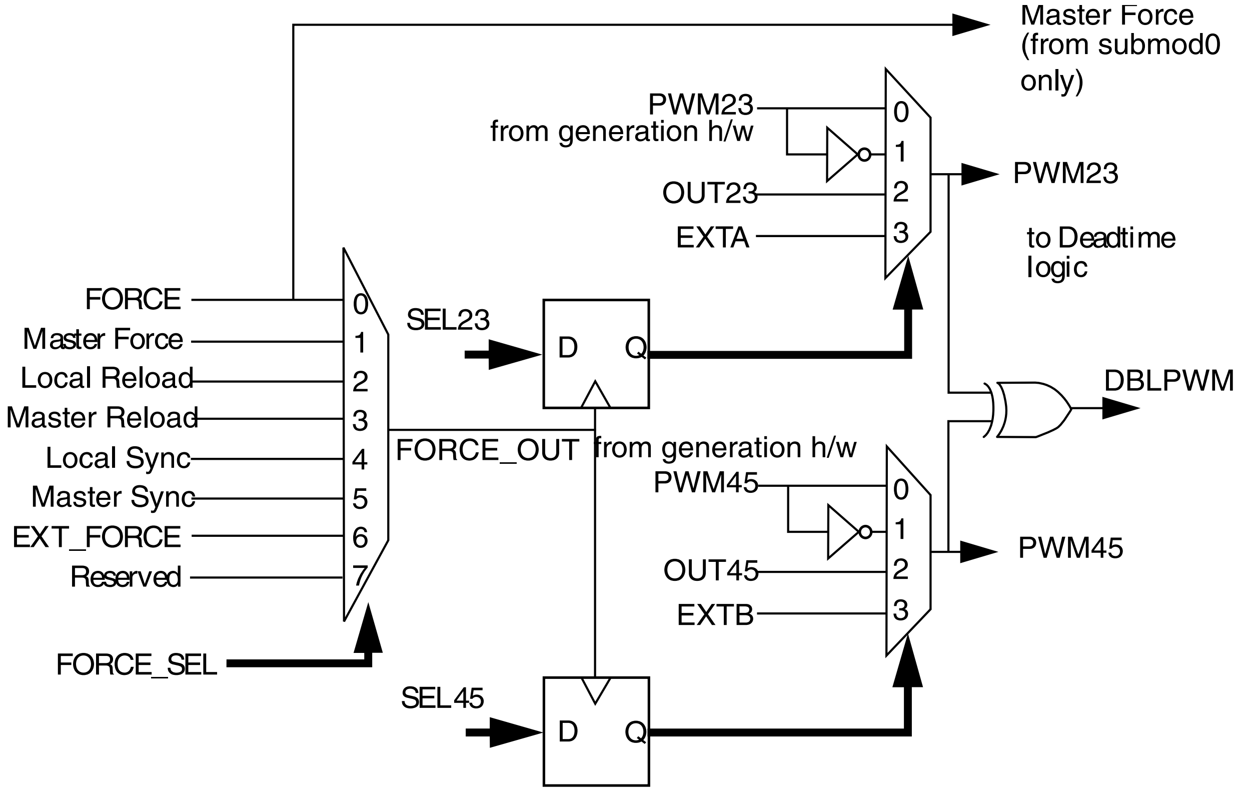

Figure 40-17. Force Out Logic

The local FORCE signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the local FORCE bit of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

40.4.2.7 Independent or Complementary Channel Operation

Writing a logic one to the INDEP bit of the CNFG register configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to the INDEP bit configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in the following figure in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by the IPOL bit.

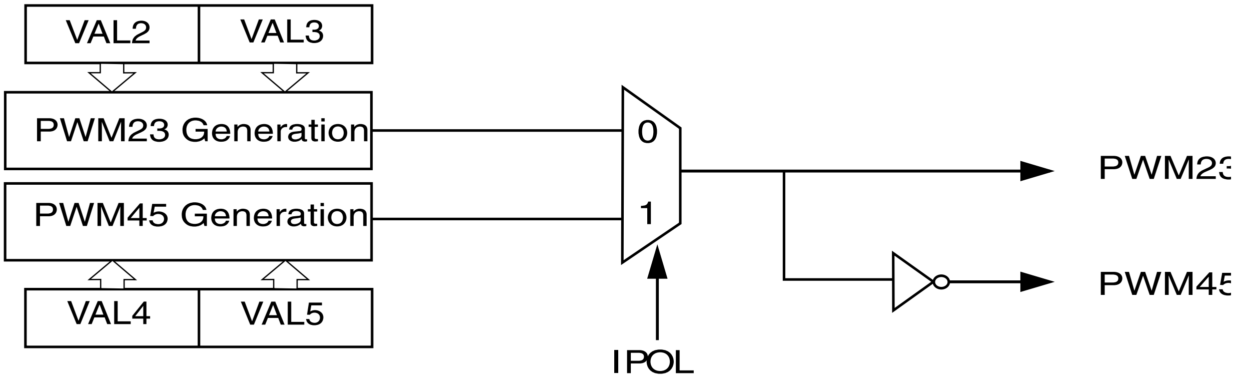

Figure 40-18. Complementary Channel Pair

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in the following figure.

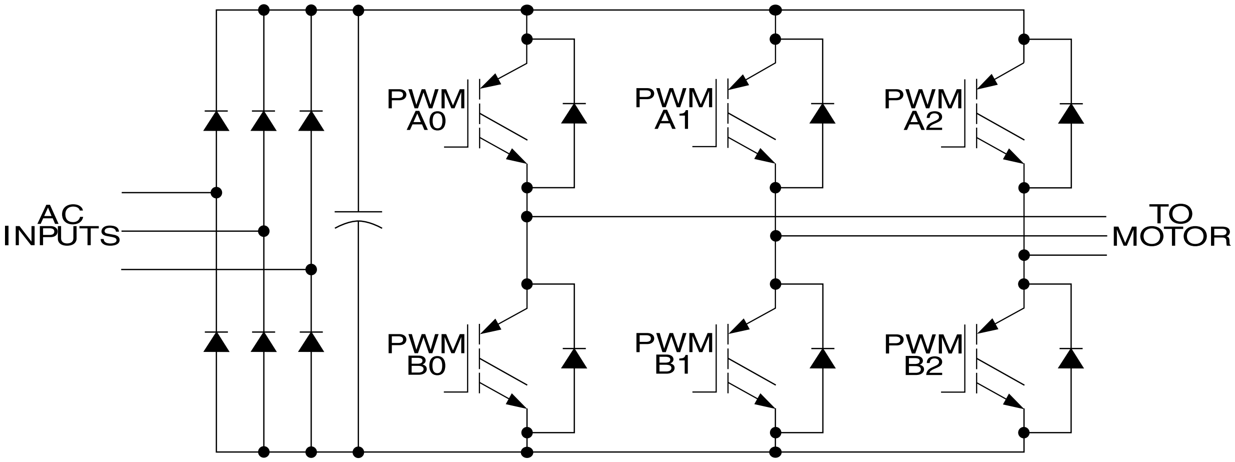

Figure 40-19. Typical 3 Phase AC Motor Drive

Complementary operation allows the use of the deadtime insertion feature.

40.4.2.8 Deadtime Insertion Logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

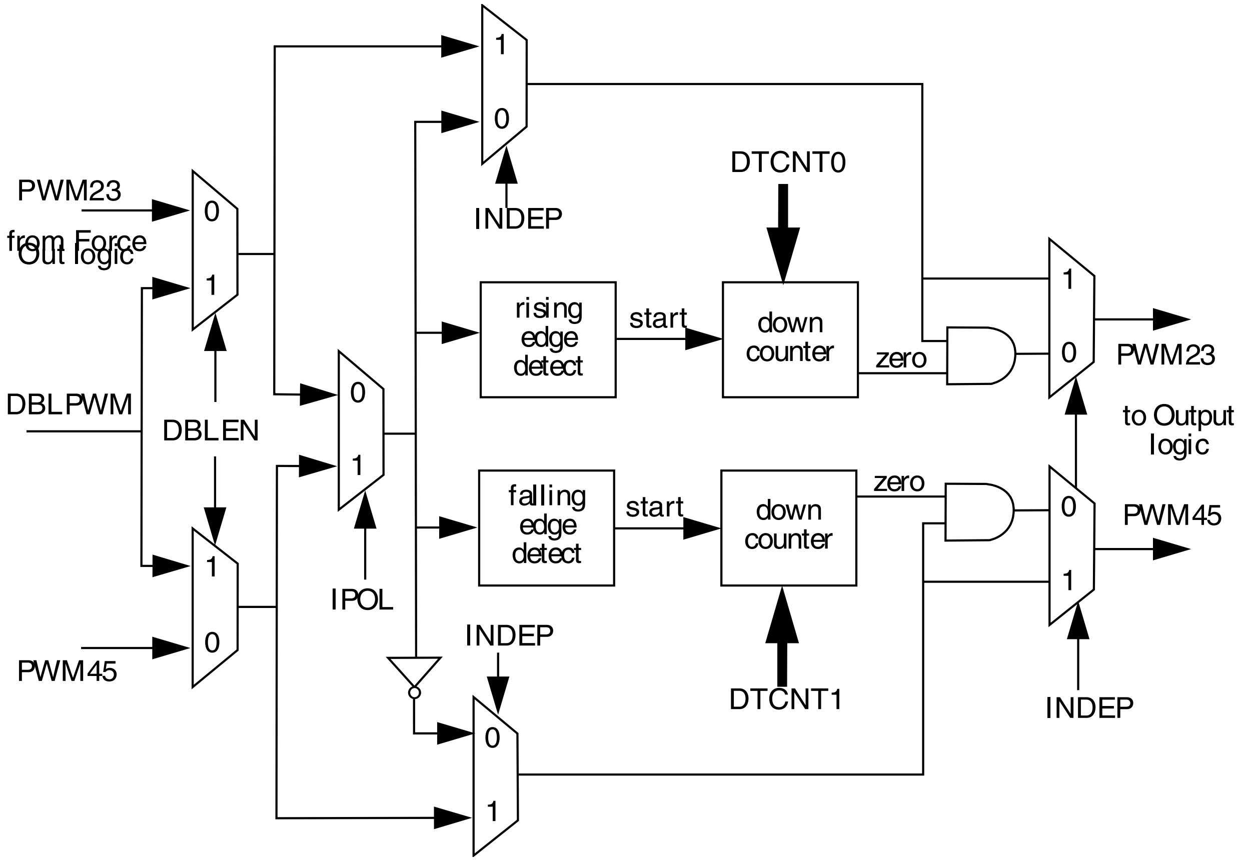

Figure 40-20. Deadtime Insertion and Fine Control Logic

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure above. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

Note

> To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. However, the transistor's characteristics may cause its switching-off time to be longer than its switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in the following figure.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of peripheral clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

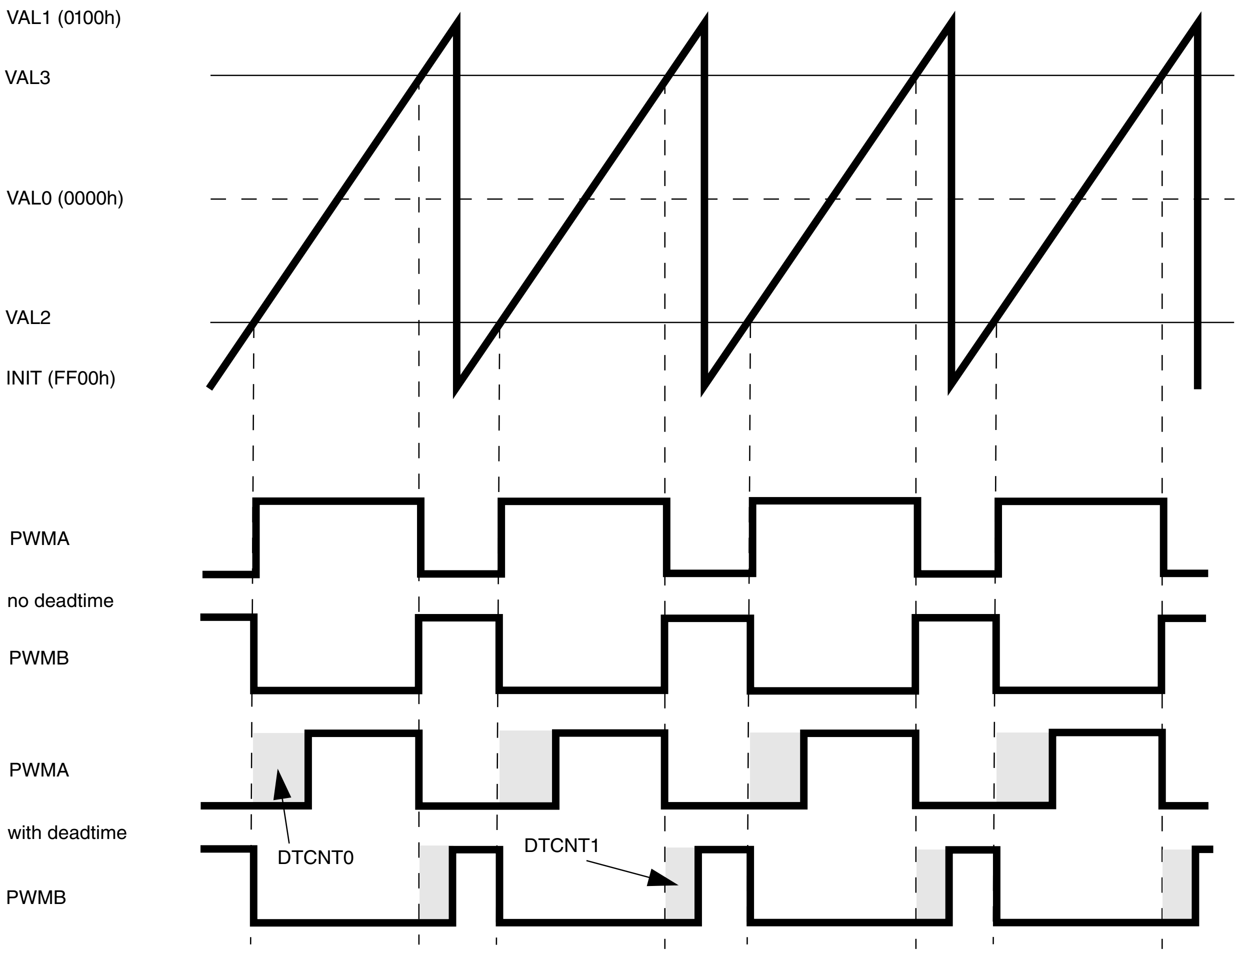

Figure 40-21. Deadtime Insertion

40.4.2.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See the following figure. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

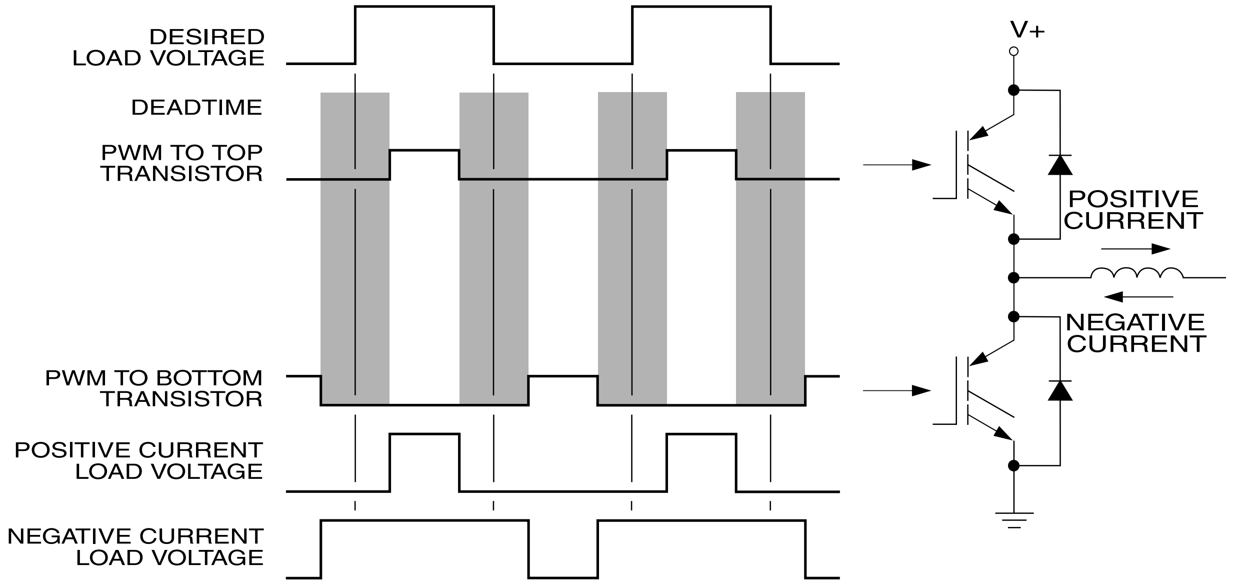

Figure 40-22. Deadtime Distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths where shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the motor current waveform. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor current for that pair. See the figure above. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the SUB*n*_VAL*x* registers. Either the SUB*n*_VAL2/SUB*n*_VAL3 or the SUB*n*_VAL4/ SUB*n*_VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the SUB*n*_VAL2/SUB*n*_VAL3 or SUB*n*_VAL4/SUB*n*_VAL5 pair is active depends on either:

- The state of the current status pin, PWMx, for that driver
- The state of the odd/even correction bit, IPOL, for that driver

To correct deadtime distortion, software can decrease or increase the value in the appropriate SUB*n*_VAL*x* register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

40.4.2.8.2 Manual Correction

To detect the current status, the voltage on each PWMx pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in the DTx bits in the CTRL1 register. The DTx bits are a timing marker especially indicating when to toggle between PWM value registers. Software can then set the IPOL bit to switch between SUB*n*_VAL2/SUB*n*_VAL3 and SUB*n*_VAL4/SUB*n*_VAL5 register pairs according to DTx values.

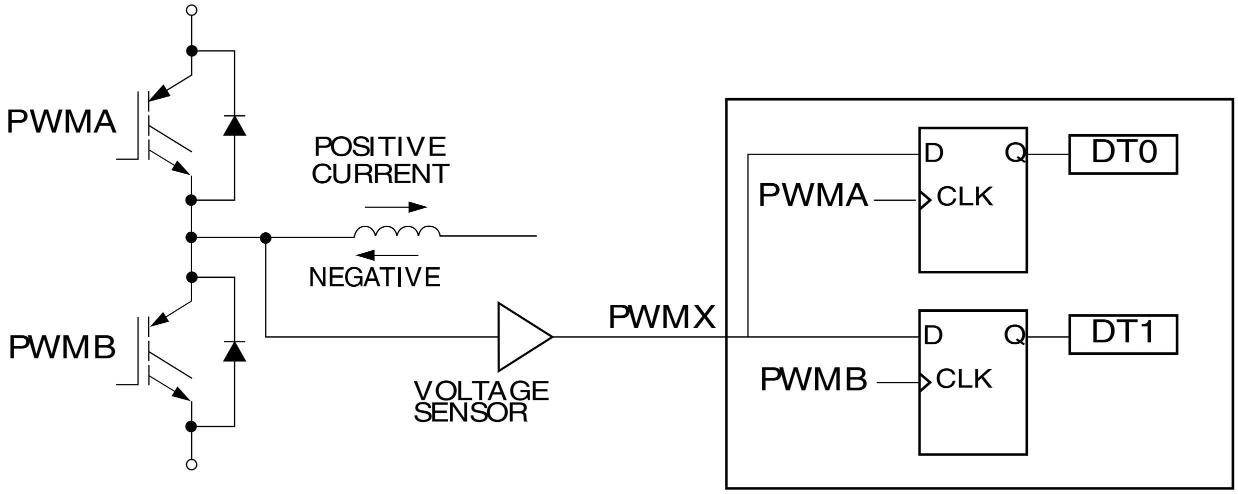

Figure 40-23. Current-status Sense Scheme for Deadtime Correction

Both D flip-flops latch low, DT0 = 0, DT1 = 0, during deadtime periods if current is large and flowing out of the complementary circuit. See the figure above. Both D flip-flops latch the high, DT0 = 1, DT1 = 1, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results will be DT0 = 0 and DT1 = 1. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

40.4.2.9 Output Logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic in the figure are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program the

POLA and POLB bits before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the PWMxFS fields.

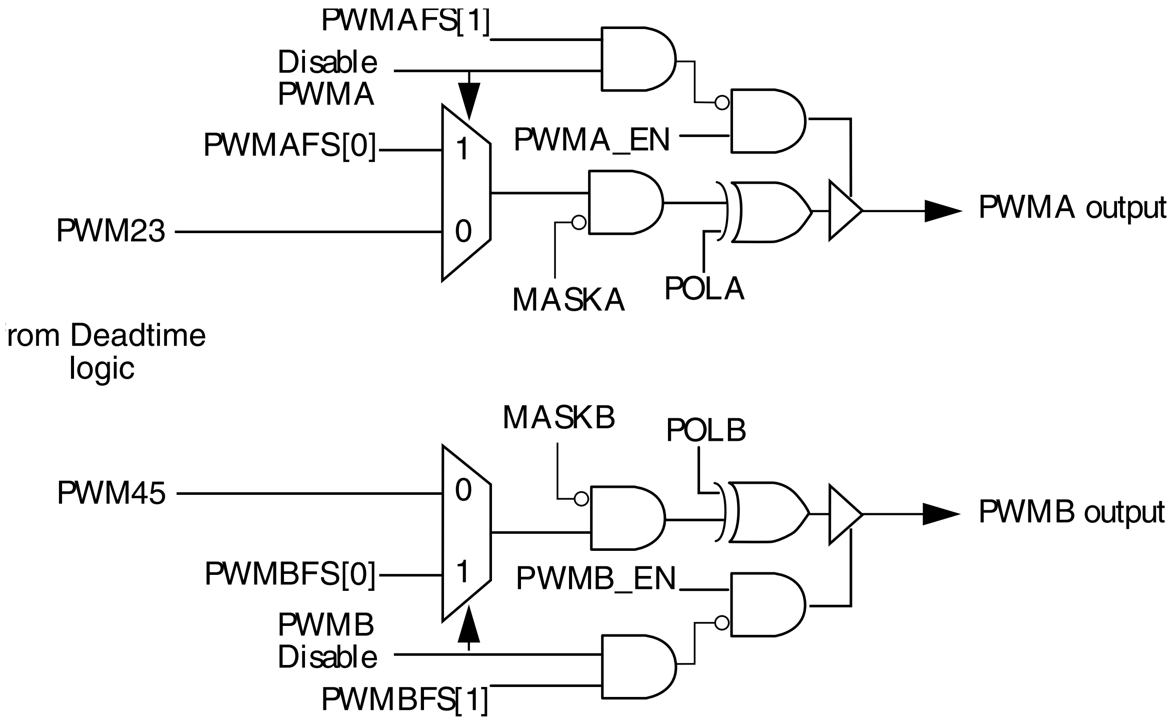

Figure 40-25. Output Logic Section

40.4.2.10 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure illustrates the block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8-bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8-bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. this feature is useful for dividing down high frequency signals for capture processing so that capture interrupts don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt after "n" events have been counted.

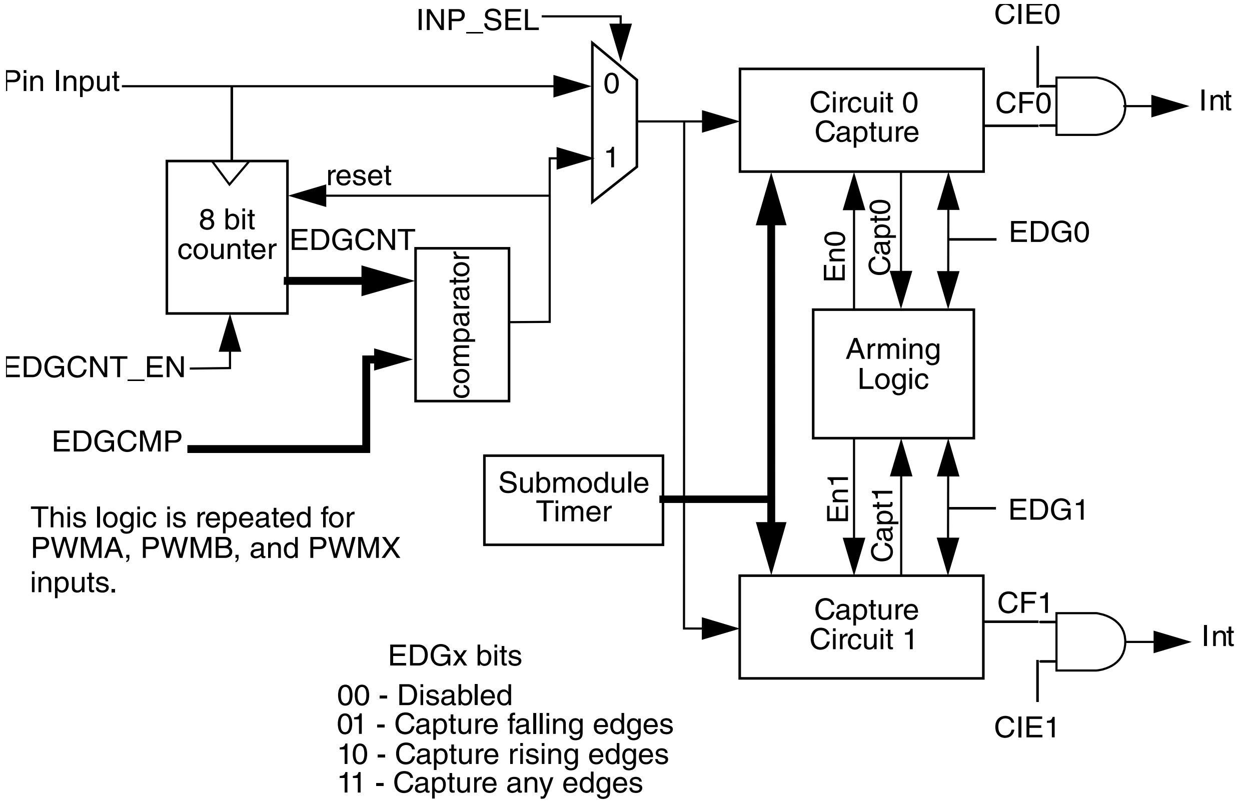

Figure 40-26. Enhanced Capture (E-Capture) Logic

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by the EDGx1 and EDGx0 bits whose functionality is listed in the figure above. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

40.4.2.11 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via the FLVL bits. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of the PWMxFS bits.

The fault decoder disables PWM pins selected by the fault logic and the disable mapping register (DISMAP). See the following figure for an example of the fault disable logic. Each bank of bits in DISMAP control the mapping for a single PWM pin. Refer to following table.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.

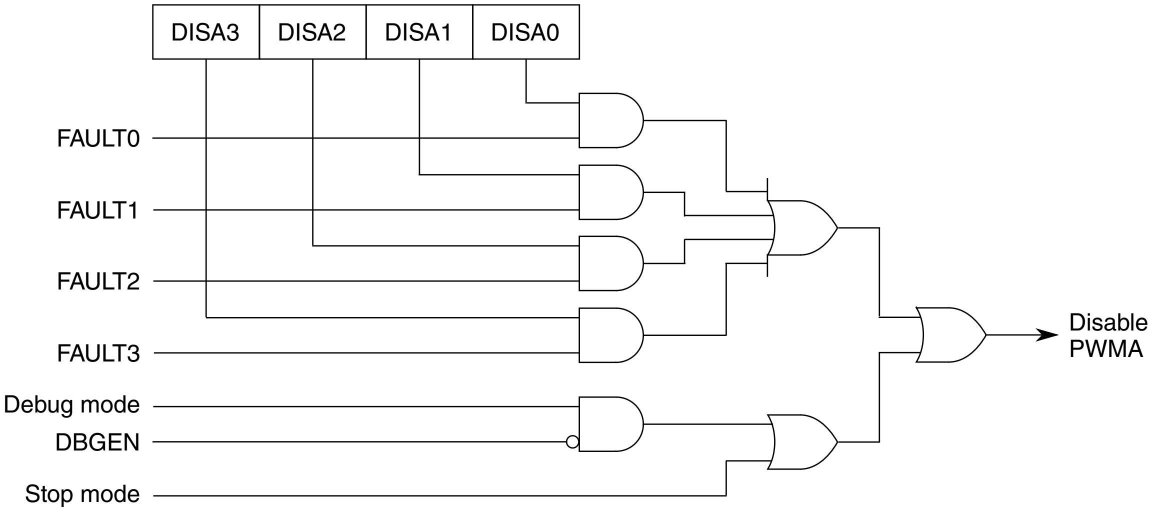

Figure 40-27. Fault decoder for PWMA

Table 40-2. Fault Mapping

PWM Pin	Controlling Register Bits
PWMA	DISA[3:0]
PWMB	DISB[3:0]
PWMX	DISX[3:0]

40.4.2.11.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with the FILT_PER field of the FFILTx register. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using the FILT_CNT field of the same register. Setting FILT_PER to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FLVLx is set), the corresponding FFPINx and fault flag, FFLAGx, bits are set. The FFPINx bit remains set as long as the filtered FAULTx pin is zero. Clear FFLAGx by writing a logic 1 to FFLAGx.

If the FIEx, FAULTx pin interrupt enable bit is set, the FFLAGx flag generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears the FFLAGx flag by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

40.4.2.11.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for automatic clearing.

When FAUTOx is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle. Clearing the FFLAGx flag does not affect disabled PWM pins when FAUTOx is set.

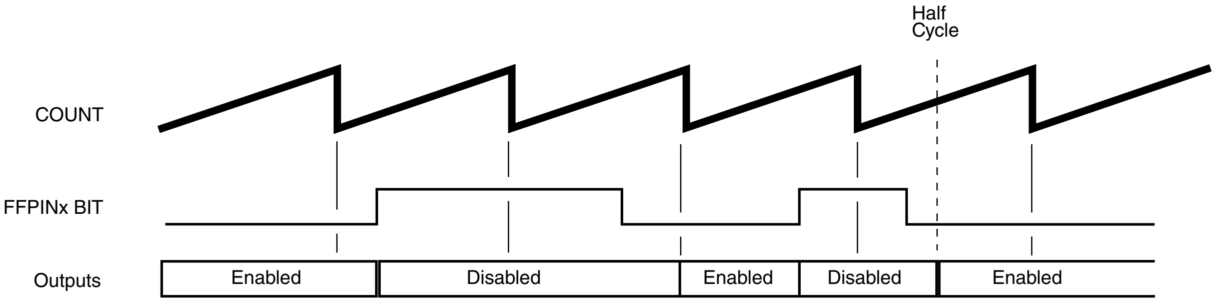

Figure 40-28. Automatic Fault Clearing

40.4.2.11.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for manual clearing:

- If the fail safe mode bits, FSAFEx, are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See the following figure. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.
- If the fail safe mode bits, FSAFEx, are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag
  - The filter detects a logic one on the FAULTx pin at the start of the next PWM full or half cycle boundary. See Figure 40-30. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.

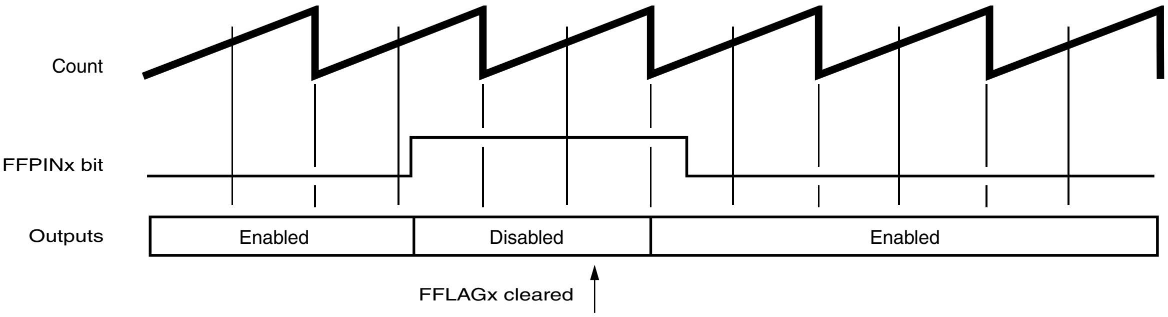

Figure 40-29. Manual Fault Clearing (FSAFE=0)

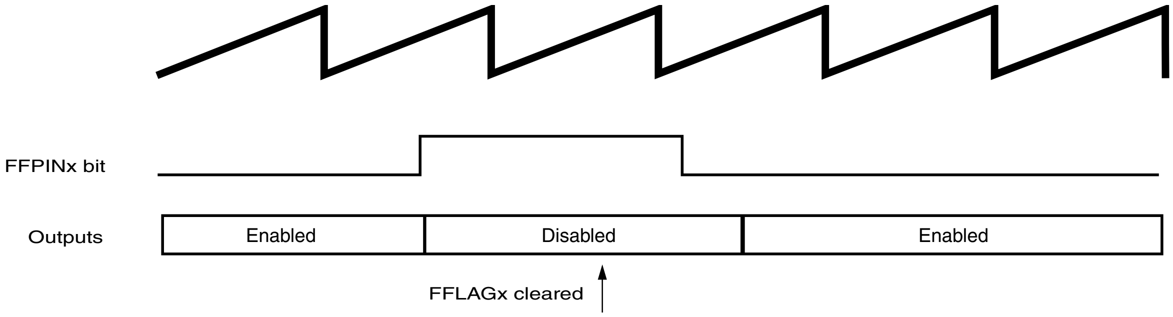

Figure 40-30. Manual Fault Clearing (FSAFE=1)

Note

> Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or EXTA and EXTB. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, RUN equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, RUN equals zero. Thus, fault clearing occurs at peripheral cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

40.4.2.11.4 Fault Testing

The FTEST bit is used to simulate a fault condition on each of the fault inputs.

40.4.3 PWM Generator Loading

This section describes load enabling, load frequency, the reload flag, reload errors, and initialization of the PWM generator.

40.4.3.1 Load Enable

The LDOK bit enables loading of the following PWM generator parameters:

- The prescaler divisor—from SUB*n*_CTRL1[PRSC]
- The PWM period and pulse width—from the SUB*n*_INIT and SUB*n*_VAL*x* registers

LDOK allows software to finish calculating all of these PWM parameters so they can be synchronously updated. SUB*n*_CTRL1[PRSC], SUB*n*_INIT and SUB*n*_VAL*x* are loaded by software into a set of outer buffers. When LDOK is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transfered to the inner set of registers immediately upon setting LDOK if LDMOD is set. Set LDOK by reading it when it is a logic zero and then writing a logic one to it. After loading, LDOK is automatically cleared.

40.4.3.2 Load Frequency

The LDFQ bits in the CTRL1 register select an integral loading frequency of one to 16 PWM reload opportunities. The LDFQ bits take effect at every PWM reload opportunity, regardless the state of the LDOK bit. The HALF and FULL bits in the CTRL1 register control reload timing. If FULL is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If HALF is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both HALF and FULL are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

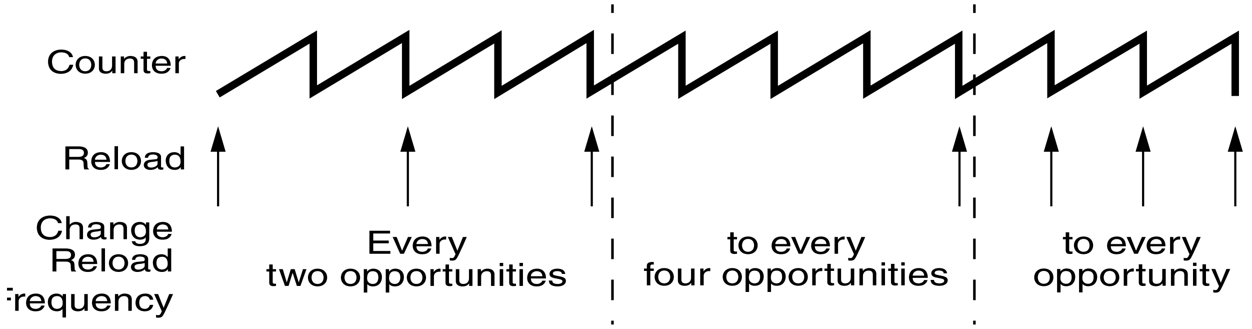

Figure 40-31. Full Cycle Reload Frequency Change

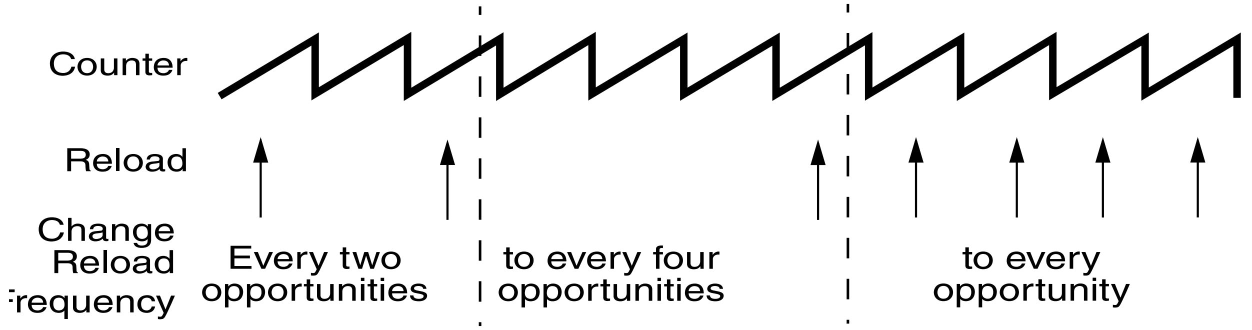

Figure 40-32. Half Cycle Reload Frequency Change

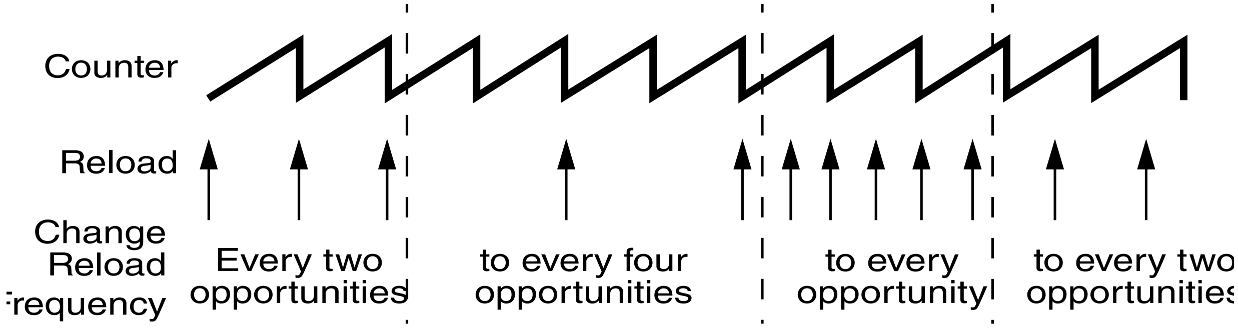

Figure 40-33. Full and Half Cycle Reload Frequency Change

40.4.3.3 Reload Flag

At every reload opportunity the PWM Reload Flag (RF) in the FlexPWM_SUBn_STS register is set. Setting RF happens even if an actual reload is prevented by the LDOK bit. If the PWM reload interrupt enable bit, RIE is set, the RF flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When RIE is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

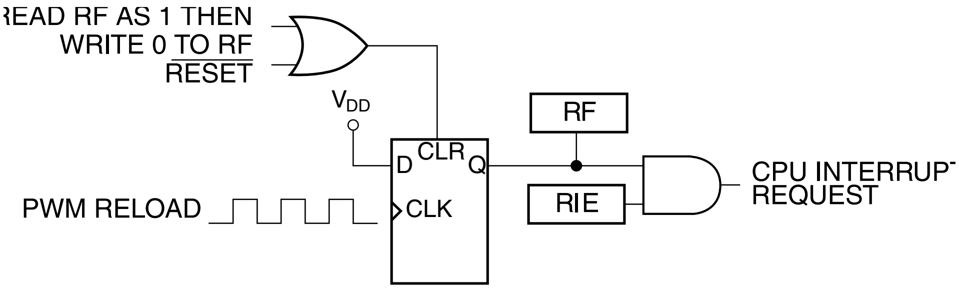

Figure 40-34. PWMF Reload Interrupt Request

40.4.3.4 Reload Errors

Whenever either SUB*n*_VAL*x* or SUB*n*_CTRL1[PSRC] is updated, the RUF flag is set to indicate that the data is not coherent. RUF will be cleared by a successful reload which consists of the reload signal while LDOK is set. If RUF is set and LDOK is clear when the reload signal occurs, a reload error has taken place and the REF bit is set. If RUF is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

40.4.3.5 Initialization

Initialize all registers and set the LDOK bit before setting the RUN bit.

Note

> Even if LDOK is not set, setting RUN also sets the RF flag. To prevent a CPU interrupt request, clear the RIE bit before setting RUN.

The PWM generator uses the last values loaded if RUN is cleared and then set while LDOK equals zero.

When the RUN bit is cleared:

- The RF flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

40.5 Resets

A reset will force all registers to their reset states and tri-state the PWM outputs.

40.6 Interrupts

Each of the submodules within the FlexPWM can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 40-3. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
ipi_int_comp0	CMPF_0	CMPIE_0	Submodule 0 compare interrupt	Compare event has occurred
ipi_int_capt0	CFX1_0, CFX0_0	CFX1IE_0, CFX0IE_0	Submodule 0 input capture interrupt	Input capture event has occurred
ipi_int_reload0	RF_0	RIE_0	Submodule 0 reload interrupt	Reload event has occurred
ipi_int_comp1	CMPF_1	CMPIE_1	Submodule 1 compare interrupt	Compare event has occurred
ipi_int_capt1	CFX1_1, CFX0_1	CFX1IE_1, CFX0IE_1	Submodule 1 input capture interrupt	Input capture event has occurred

Table continues on the next page...

Table 40-3. Interrupt Summary (continued)

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
ipi_int_reload1	RF_1	RIE_1	Submodule 1 reload interrupt	Reload event has occurred
ipi_int_comp2	CMPF_2	CMPIE_2	Submodule 2 compare interrupt	Compare event has occurred
ipi_int_capt2	CFX1_2, CFX0_2	CFX1IE_2, CFX0IE_2	Submodule 2 input capture interrupt	Input capture event has occurred
ipi_int_reload2	RF_2	RIE_2	Submodule 2 reload interrupt	Reload event has occurred
ipi_int_comp3	CMPF_3	CMPIE_3	Submodule 3 compare interrupt	Compare event has occurred
ipi_int_capt3	CFX1_3, CFX0_3	CFX1IE_3, CFX0IE_3	Submodule 3 input capture interrupt	Input capture event has occurred
ipi_int_reload3	RF_3	RIE_3	Submodule 3 reload interrupt	Reload event has occurred
ipi_int_rerr	REF_0	REIE_0	Submodule 0 reload error interrupt	Reload error has occurred
	REF_1	REIE_1	Submodule 1 reload error interrupt	
	REF_2	REIE_2	Submodule 2 reload error interrupt	
	REF_3	REIE_3	Submodule 3 reload error interrupt	
ipi_int_fault	FFLAG	FIE	Fault input interrupt	Fault condition has been detected

40.7 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered SUB*n*_VAL*x* registers.

Table 40-4. DMA Summary

DMA Request	DMA Enable	Name	Description
Submodule 0 read request	CX0DE_0	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_0	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_0	Capture FIFO read request source select	Selects source of read DMA request
Submodule 0 write request	VALDE_0	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated
Submodule 1 read request	CX0DE_1	Capture FIFO X0 read request	CVAL0 contains a value to be read

Table continues on the next page...

Table 40-4. DMA Summary (continued)

DMA Request	DMA Enable	Name	Description
	CX1DE_1	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_1	Capture FIFO read request source select	Selects source of read DMA request
Submodule 1 write request	VALDE_1	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated
Submodule 2 read request	CX0DE_2	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_2	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_2	Capture FIFO read request source select	Selects source of read DMA request
Submodule 2 write request	VALDE_2	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated
Submodule 3 read request	CX0DE_3	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_3	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_3	Capture FIFO read request source select	Selects source of read DMA request
Submodule 3 write request	VALDE_3	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated

Chapter 41
Cross-Triggering Unit (CTU)

41.1 Introduction

NOTE

> For the chip-specific implementation details of this module's instances, see the chip configuration information.

In PWM driven systems it is important to schedule the acquisition of the state variables with respect to the PWM cycle. State variables are obtained through the following peripherals: ADC, position counter (for example, quadrature decoder, resolver, and sine-cos sensor), and PWM duty cycle decoder.

The Cross-Triggering Unit (CTU) is intended to completely avoid CPU involvement in the acquisition of state variables during a control cycle defined by the PWM cycle, the half PWM cycle, or a multiple number of PWM cycles. Several CTU registers are double-buffered, thus allowing coherent update during the transition from one control cycle to the next. Thus double-buffered registers updated at control cycle N will be updated during the transition from control cycle N to control cycle N+1.

The CTU provides four FIFO memory blocks to temporarily store ADC results for CPU access.

41.2 Block diagram

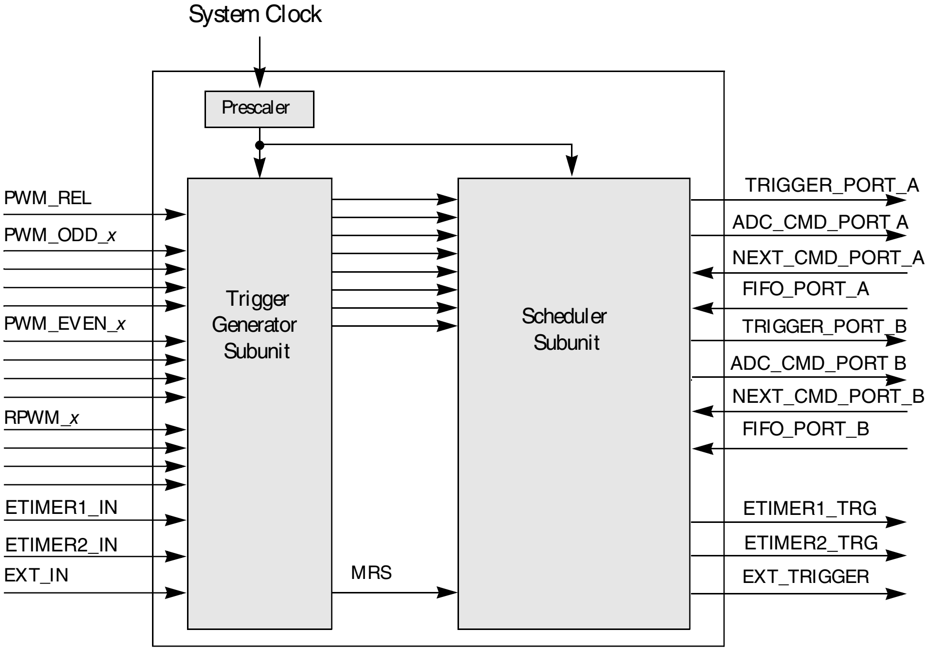

Figure 41-1. CTU block diagram

41.3 CTU overview

The CTU receives several signals from different sources such as PWM, timers, position decoder, and/or external pins. These signals are then processed to generate up to eight trigger events. An input event can be a rising edge, a falling edge, or both edges of the incoming signal. The output can be a pulse, an ADC command, or a stream of consecutive ADC commands for oversampling support. The outputs are targeted to one or more peripherals such as ADCs and timers.

The CTU implements the following features:

- Cross triggering between ADC, PWM timers, on-chip general purpose timers, and external pins
- Double-buffered trigger unit that generates up to 8 triggers
- Trigger generation unit configurable in sequential or triggered modes
- Trigger delay functionality to compensate for the delay of external low pass filters
- Double-buffered ADC command list pointers
- Double-buffered ADC conversion command list
- Each trigger has the capability to generate consecutive conversion commands

- ADC conversion commands allow two ADCs to be controlled synchronously with queue selection to store conversion results
- DMA support

In a typical application, the CTU interfaces with the following peripherals:

- PWM generators for motor control
- Timers
- External signals

The inputs are 16 digital signals. The CTU detects the rising and/or falling edges for each one of them.

Figure 41-1 shows a high level CTU block diagram. The CTU hardware architecture consists of two subunits:

- Trigger generator subunit
- Scheduler subunit

The Trigger generator subunit receives CTU input signals and selects the active edges in order to generate the Master Reload signal. The Master Reload is used to load several CTU double buffered registers. See sections TGS in triggered mode and TGS in sequential mode for more details about the Master Reload signal. The Trigger generator subunit also generates up to eight trigger event signals which are used by the Scheduler subunit.

The Scheduler subunit generates the trigger event output according to the trigger event signals from the Trigger generator subunit. The trigger event output starts an ADC conversion or generates output signals to trigger events for IPs in the SoC. See section Scheduler subunit (SU) for more detail about the Scheduler subunit.

41.3.1 Interaction with other peripherals

The following figure shows an example of how the CTU interacts with on chip peripherals.

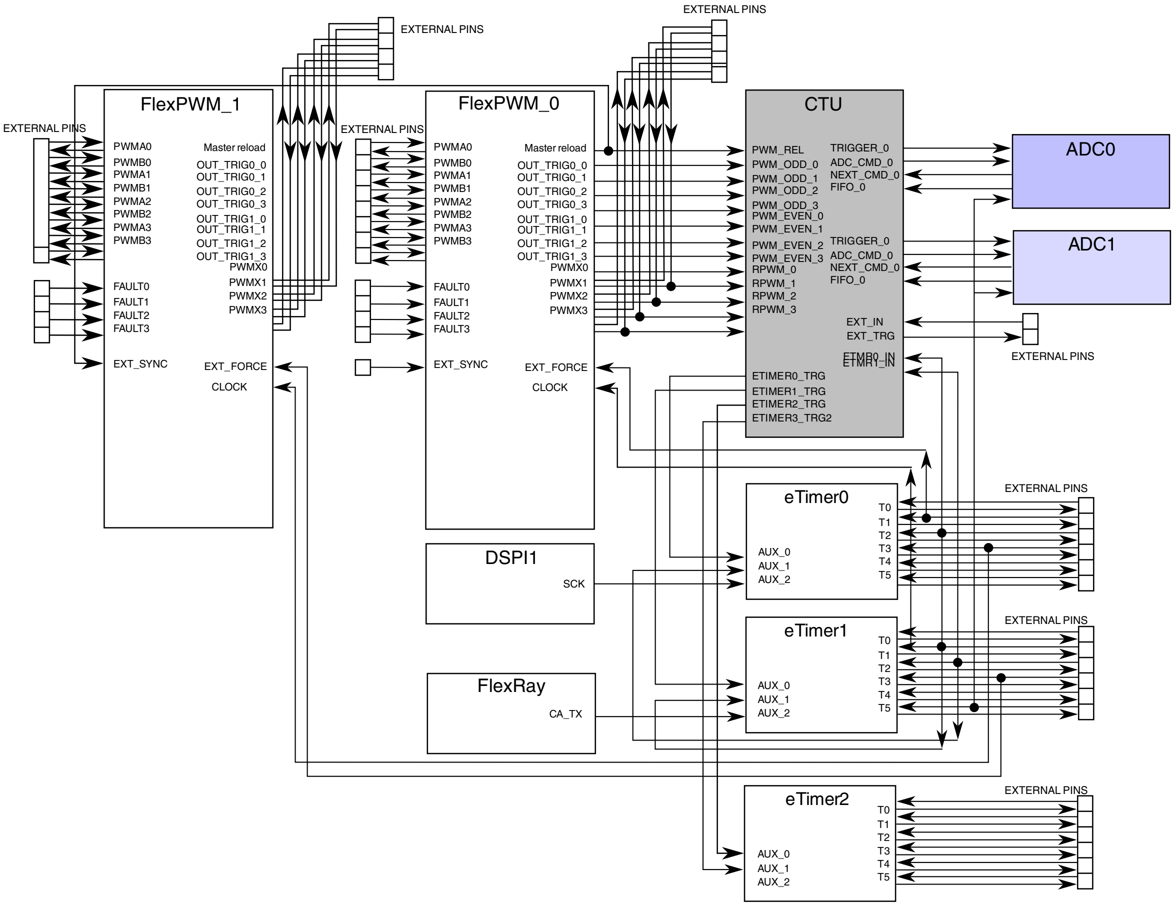

Figure 41-2. CTU application example: interaction with other peripherals

NOTE

For the specific manner in which the CTU interacts with other peripherals on your particular device, see the device configuration details.

41.3.2 Modes of operation

The CTU has two main modes of operation:

1. Triggered mode: the input event from the CTU interface is used to generate a sequence of up to 8 triggers to several outputs such as the ADCs, timers, and external triggers. Internal sequencer logic is used to schedule the triggers based upon the input event occurrence.
2. Sequential mode: each input event generates only one trigger for the selected output, such as ADCs, timers, and external triggers.

41.4 Signal description

The following table shows the chip-level signals for the CTU module.

Table 41-1. Signal properties

Name	Function
EXT_IN	Input pin for external triggers
EXT_TRG	Output pin for external triggers

41.5 Memory Map and Registers

CTU registers are implemented in two sizes:

- 32-bit registers: byte access for write operations and 32-bit access for read operation
- 16-bit registers: byte access for write operations and 32-bit access for read operations

If a 32-bit write operation is performed over a 16-bit register, the write operation is performed on the 4 aligned bytes. Read operation should be performed only at 32-bit boundary.

NOTE

Reserved bit registers, when available for write operations, should be written always with logic 0. Read access does not return meaningful data from reserved bit registers. This module does not issue transfer errors when trying to access its reserved locations.

NOTE

If the system attempts to access an invalid address within the CTU memory map, such as a non-existent register, it does not assert a slave bus error signal to the system. So the user should not rely on such an error when accessing the CTU.

The following tables describe the CTU memory mapped registers.

CTU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Trigger Generator Subunit Input Selection Register (CTU_TGSISR)	32	R/W	0000_0000h	41.5.1/1214

41.5.1 Trigger Generator Subunit Input Selection Register (CTU_TGSISR)

The TGSISR register is double buffered. The load from the corresponding buffer to the register is controlled by the TGSISR_RE bit in the CTU_CR register. The TGSISR_RE bit is self negated. Once set, this bit remains set until the TGSISR register is updated from the corresponding buffer register. Reads to the TGSISR register actually return the content of the buffer and not the content of the register. Thus, a read will return the most recent data written to the register address even though the buffer data is not synchronized with the register data.

NOTE

For the particular input connection assigned to each field in this register, see the CTU's chip-specific configuration details.

16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 T5_INDEX	Trigger 5 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 T4_INDEX	Trigger 4 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23.

41.5.8 Trigger Handler Control Register 1 (CTU_THCR1)

The THCR1 register is double buffered. The update from the corresponding buffer register is controlled by the MRS signal. The THCR1 and THCR2 registers are together organized into 8 groups of 7 enable bits. Each group is associated with one trigger from the Trigger subunit. Each group of enable bits has 7 enables corresponding to a master trigger enable, External Trigger output enable, 4 eTimer outputs, and the ADC command list enable, respectively. If the master trigger enable Tn_E is cleared, the trigger is disabled and the other trigger enable bits in the group have no effect.

41.5.10 Commands List Register A for ADC single-conversion mode commands (CTU_CLR_A_*n*)

The Command List Register (CLR_x_n), where n = 1,.......,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its CMS and ST0 bits. If CMS=0 and ST0=0, the single conversion mode is selected and the CLR register assumes the CLR_A_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CIR	LC	CMS	FIFO			ST0	0			SU	0	CH			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_CLR_A_*n* field descriptions

Field	Description
0 CIR	Command execution Interrupt Request enable bit. 0 Disabled 1 Enabled
1 LC	Last Command bit. 0 Not last 1 Last
2 CMS	Conversion Mode Selection. Must be 0 in this register format. 0 Single conversion mode 1 Dual conversion mode
3–5 FIFO	FIFO used for ADC Port A / Port B. See CLR_A[SU] bit for Port A versus Port B selection. 000 FIFO_0 select ---- ------------------- 111 FIFO_7 select

Table continues on the next page...

CTU_CLR_A_*n* field descriptions (continued)

Field	Description
6 ST0	Self Test mode control 0. Must be 0 in this register format.
7–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 SU	ADC Port A / Port B selection. 0 ADC Port A selected 1 ADC Port B selected
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 CH	ADC Port channel number.

41.5.11 Command List Register B for ADC dual-conversion mode commands (CTU_CLR_B_*n*)

The Command List Register (CLR_x_n), where n = 1,.......,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its CMS and ST0 bits. If CMS=1 and ST0=0, the dual conversion mode is selected and the CLR register assumes the CLR_B_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where i=0d to 23d

3–5 FIFO	FIFO used for ADC Port A / Port B. See CLR_A[SU] bit for Port A versus Port B selection. 000 FIFO_0 select --- ------------------- 111 FIFO_7 select
6 ST0	Sel-Test mode control 0. Must be 0 in this register format.
7–10 CH_B	ADC Port B channel number.
11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 CH_A	ADC Port A channel number.

41.5.12 Command List Register C for self-test commands (CTU_CLR_C_*n*)

The Command List Register (CLR_x_n), where n = 1,.......,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its ST0 bit. You must first set ST0 to 1 to set the CLR register in the self-test mode register format. In this case, the CLR register assumes the CLR_C_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7
Read Write	CIR	LC	ST1	ST_CMS	ST_SU	0	ST0	ALG

41.5.13 FIFO DMA Control Register (CTU_FDCR)

The FDCR register enables the DMA requests issued by the CTU FIFOs. The DMA request occurs when it is enabled and the corresponding FIFO had reached a threshold defined in register FTH.

NOTE

Interrupt and DMA are controlled independently, thus FIFO DMA operation and interrupts can be enabled at the same time.

Address: 0h base + 6Ch offset = 6Ch

Field	Description
	0 Disabled 1 Enabled
15 DE0	FIFO 0 DMA enable. 0 Disabled 1 Enabled

41.5.14 FIFO Control Register (CTU_FCR)

This register implements interrupt enable bits to signal FIFO behavior. FIFO overrun, overflow, empty, and full indication from one of the FIFOs are OR-ed together to indicate through one interrupt line that one or more flags are active. After receiving an interrupt the FST register should be checked to evaluate what caused that interrupt. There is one interrupt line per FIFO module.

Address: 0h base + 70h offset = 70h

31 FULL_EN0	FIFO 0 Full interrupt enable. 0 Disabled 1 Enabled

41.5.15 FIFO Threshold Register (CTU_FTH)

This register defines the threshold value for four FIFO modules. The threshold is used for comparison against the FIFO pointer and to evaluate if an overflow condition occurred for that FIFO. The overflow flag indicates that a certain amount of data, defined by the threshold value, is available in the FIFO for read. The overflow condition is set if the number of elements in the FIFO is greater than the threshold value. Thus, out of reset this register is set to detect one element in the respective FIFO since the initial value is zero.

NOTE

The threshold value should not exceed the FIFO size

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CTU_FTH field descriptions

Field	Description
0–7 TH3	FIFO 3 Threshold.
8–15 TH2	FIFO 2 Threshold.
16–23 TH1	FIFO 1 Threshold.
24–31 TH0	FIFO 0 Threshold.

41.5.16 FIFO Status Register (CTU_FST)

This register has the flags that indicate the status of the FIFO modules. Up to four FIFOs are supported. FIFO overrun, overflow, empty, and full flags are available. If enabled by the FCR register bits, these flags can generate an interrupt to the CPU. There is one interrupt signal per FIFO which combines overrun, overflow, empty, and full flags.

NOTE

The only actual error indication corresponds to the overrun flags which stay asserted once the overrun condition occurs. They are cleared by writing 1 to the respective flag. The overflow, empty, and full flags correspond to the current state of the FIFOs.

NOTE

Bits OR3, OR2, OR1, and OR0 can be read and cleared by software

Address: 0h base + 7Ch offset = 7Ch

Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

CTU_EFR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 LIST_BE	List Busy Error. Indicates that a list of commands is trying to send commands to a busy ADC or to the same ADC at the same time. It also indicates a conflict in the self-test algorithm execution by the ADCs, see Self-Test Execution Errors section. Cleared if 1 is written to this bit location. 0 No error 1 Error
3 CS	Self test Counter Status. This bit indicates if a self-test algorithm is in progress. If 1 is written to this bit, a reset to the self test counter will occur, thus terminating the self-test algorithm execution. As a status bit it indicates: 0 All the counters are at reset value, thus none of the self-test algorithm are executing 1 One of the counters used in self test mode is not in the reset state, thus self-test is in progress.
4 ET_OE	External Trigger generation Overrun Error. This bit is set when an external trigger occurs while a trigger input is being processed by the TGS. It is cleared if 1 is written to this bit location. 0 No error 1 Error
5 ERRCMP	Error Compare. When a match occurs, the TGS Counter has reached the TGSCCR value. Cleared if 1 is written to this bit location.

Table continues on the next page...

CTU_EFR field descriptions (continued)

Field	Description
	0 No match 1 Match
6 T4_OE	Timer 4 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
7 T3_OE	Timer 3 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
8 T2_OE	Timer 2 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
9 T1_OE	Timer 1 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
10 ADC_OE	ADC command generation Overrun Error. This bit is set if an ADC command is issued when there is a command already being processed. Cleared if 1 is written to this bit location. 0 No Error 1 Error
11 TGS_OSM	The TGS Overrun in Sequential Mode. This bit is set when a new event occurs before the trigger event selected by the previous event had occurred. The error is generated only if the trigger from the TGS is linked to a SU output. Cleared if 1 is written to this bit location. 0 No overrun 1 Overrun
12 MRS_O	Master Reload Signal Overrun. If the time window defined by two consecutive MRS is not enough for the number of programmed events in the THCR registers, an error occurs and MRS_O flag is set. Cleared if 1 is written to this bit location. 0 No overrun 1 Overrun
13 ICE	Invalid Command Error. An error that occurs when the shared channel is accessed by two ADCs at the same time, or when an ADC is already using the channel. This situation can occur with a dual conversion command or with two single conversions in parallel mode. 0 No error 1 Error
14 SM_TO	Trigger Overrun (more than 8 ES) in TGS Sequential Mode. If the number of positive edges of ES is higher than 8, an error occurs and SM_TO flag is set. Cleared if 1 is written to this bit location. 0 No overrun 1 Overrun

Table continues on the next page...

CTU_EFR field descriptions (continued)

Field	Description
15 MRS_RE	Master Reload Signal Reload Error. If an MRS occurs while the user is updating a double-buffered register, the MRS_RE is set indicating an error condition. Cleared if 1 is written to this bit location. 0 No error 1 Error

41.5.20 Interrupt Flag Register (CTU_IFR)

The IFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

NOTE

The Tn_I fields read 0 at reset. When reset is released, these fields remain cleared until the CTU timer clock is enabled. After the CTU timer clock is enabled, the Tn_I fields read 1. These flags must be cleared before enabling the interrupt requests.

Address: 0h base + C2h offset = C2h

Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

CTU_IFR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 SERR_B	If this bit is set, it means that the time between the start of a conversion and the end of that conversion is out of the expected range which is defined by the EXPBR and CNTRNGR registers. See Expected Value B (EXPBR) and Counter Range (CNTRNGR) registers. Cleared if 1 is written to this bit location.
5 SERR_A	If this bit is set, it means that the time between the start of a conversion and the end of that conversion is out of the expected range defined by the EXPAR and CNTRNGR registers. See the Expected value A (EXPAR) and Counter Range (CNTRNGR) registers. Cleared if 1 is written to this bit location.
6 ADC_I	ADC command interrupt flag is set when a new command is issued. The interrupt related to this flag is enabled by the CIR bit in the CLR_x_n registers. Cleared if 1 is written to this bit location.

Table continues on the next page...

CTU_IFR field descriptions (continued)

Field	Description
7 T7_I	Trigger 7 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
8 T6_I	Trigger 6 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
9 T5_I	Trigger 5 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
10 T4_I	Trigger 4 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
11 T3_I	Trigger 3 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
12 T2_I	Trigger 2 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
13 T1_I	Trigger 1 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
14 T0_I	Trigger 0 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
15 MRS_I	MRS Interrupt flag is set when the Master Reload Signal occurs. The interrupt associated with this flag is enabled by the MRS_IE bit in the IR register. Cleared if 1 is written to this bit location.

CTU_COTR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 COTGT	Control ON-Time and Guard Time for external trigger. See Scheduler subunit (SU) for a more detailed description.

41.5.23 Control Register (CTU_CR)

NOTE

The CTU_ADC_R bit resets all lists in execution. If CTU list execution is in parallel mode, this bit resets both lists even if they issued commands to different ADCs. Also, the self-test algorithm counters go to reset state.

NOTE

Bits Tn_SG, CTU_ADC_R, CGRE, and MRS_SG can be set by software. Bits CTU_ODIS, DFE, GRE, and TGSISR_RE can be read and set by software.

CTU_EXPBR field descriptions

Field	Description
0–15 EXPB	This value is the expected number of system clock cycles needed by ADC Port B to complete a conversion.

41.5.27 Counter Range Register (CTU_CNTRNGR)

The CNTRNGR register provides a way to mask out the less significant bits in the EXP_A and EXP_B fields of EXPAR and EXPBR registers, respectively. If set, bits in CNTRNG mask out related bits in EXP_A and EXP_B fields, thus providing a range in which a conversion should occur. The expression used for the conversion range check is: set SERR_A bit if (conversion counter & ~CNTRNG > EXP_A & ~CNTRNG) or (conversion counter & ~CNTRNG < EXPP_A & ~CNTRNG), where the conversion counter increments at system clock rate (slave bus clock rate). This equation also applies to SERR_B and EXP_B.

NOTE

The 1s in the CNTRNG must be set from the right to the left (less significant bits) without gap with 0.

NOTE

The safety counter allowed range is obtained by taking the EXPA/B value and exchanging to "X" the corresponding positions where the CNTRNG bit is 1.

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								CNTRNG

CTU_CNTRNGR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 CNTRNG	If set, the bits in this field mask out the equivalent bits of the expected values EXP_A and EXP_B. In this way, a range of system clock (slave bus clock) cycles is defined for a conversion to occur. This means the bit positions with 1s in the CNTRNG change the corresponding bits on EXPA/EXPB and safety counters A/B to "X". For example, with EXPA = 1b0010_1101 and CNTRNG = 0b0111, the safety counter can end with values of the format 0b0010_1XXX to avoid SERR_A error flag.

41.6 Functional description

The CTU is comprised by two subunits: the Trigger Generator subunit, or TGS, and the Scheduler subunit, or SU. The TGS is responsible for generating triggers based on the module input signals connected to timer modules. The trigger signal from TGS is then connected to the scheduler subunit, which is responsible for the generation of ADC commands or triggers to on-chip logic such as timers. The following sections describe the TGS and SU in more detail.

41.6.1 Trigger Generator subunit (TGS)

The Trigger Generator subunit, TGS, generates up to eight trigger events. The main sub-blocks in the TGS are:

- Counter: generates sequential trigger events
- Trigger List: with 8 x 16-bit double-buffered registers for timing comparison

The TGS has two modes of operation:

- **Triggered mode**: each event source generates up to eight trigger event outputs.
- **Sequential mode**: each event source generates only one trigger event output.

Note

> An *event* means a pulse generated from the selected CTU trigger inputs. It is represented in Figure 41-5 by the ES signal (event signal).

External signals, represented by EXT_IN in Figure 41-5, may be asynchronous related to the CTU clock. For this reason the external trigger inputs are filtered by a CTU programmable digital filter. The external signal is considered at 1 if it is stable at 1 during FILTER_N CTU clock cycles and it is considered to be at 0 if it is stable at 0 during FILTER_N CTU clock cycles, where FILTER_N is defined in the digital filter register (DFR).

Trigger events can be initiated by hardware or by software. A software trigger is generated by writing to the CTU Control Register, CR. The CR register Tx_SG bits are automatically cleared by the CTU hardware when the respective trigger event is generated.

41.6.2 TGS in triggered mode

Figure 41-3 shows the TGS configuration in Triggered mode.

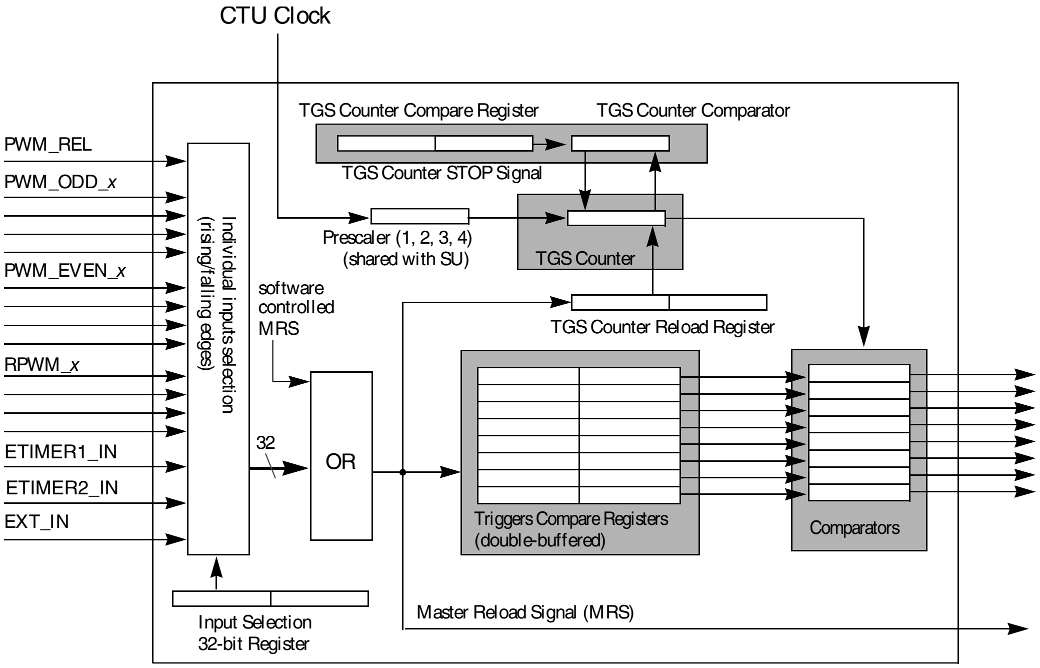

Figure 41-3. Trigger Generator subunit in triggered mode

Note

> The CTU clock should be connected to the same clock source used by the CTU inputs clock. In Figure 41-3 these inputs are from the PWM generator, eTimers, and EXT_IN.

The TGS has 16 input signals selected from the input selection register (TGSISR). The available selections are:

- Inactive, no selection
- Rising edge
- Falling edge
- Both edges

Up to 32 input events corresponding to 16 input signals are selected through the TGSISR register and OR-ed in order to generate the Master Reload Signal (MRS), which defines a *control cycle*.

The MRS can also be generated by software. The software operation is done by writing to the MRS_SG bit in the CTU Control Register. The MRS_SG bit is self cleared; thus, it reads always as 0. The MRS is used to re-load the TGS Counter Register with the values from the double-buffered TGSCRR register. The MRS is also used to re-load all double-buffered registers, such as the trigger compare registers, TGSCR and TGSCRR, with the corresponding buffered values.

The triggers list registers consist of 8 compare registers (T0CR through T7CR). Each register is associated with a comparator, where a match generates an output trigger. On the occurrence of a re-load triggered by MRS, the comparison for trigger events generation starts from the first cycle of counting. However, the comparison with the TGS Counter Compare Register (TGSCCR) is always disabled during one TGS clock cycle and then re-enabled. A match between TGSCCR and the TGS counter stops the TGS counter. Therefore, this one cycle disable allows the user to configure the TGSCCR and TGSCRR with the same value.

The prescaler for TGS and SU is defined by the PRES bits in the TGS Control Register and divides the CTU clock. The available selections for the prescaler values are 1, 2, 3, and 4.

Figure 41-4 shows a timing diagram for the TGS operation in triggered mode. The MRS and the trigger event occurrences are indicated along with the delay relative to the MRS occurrence.

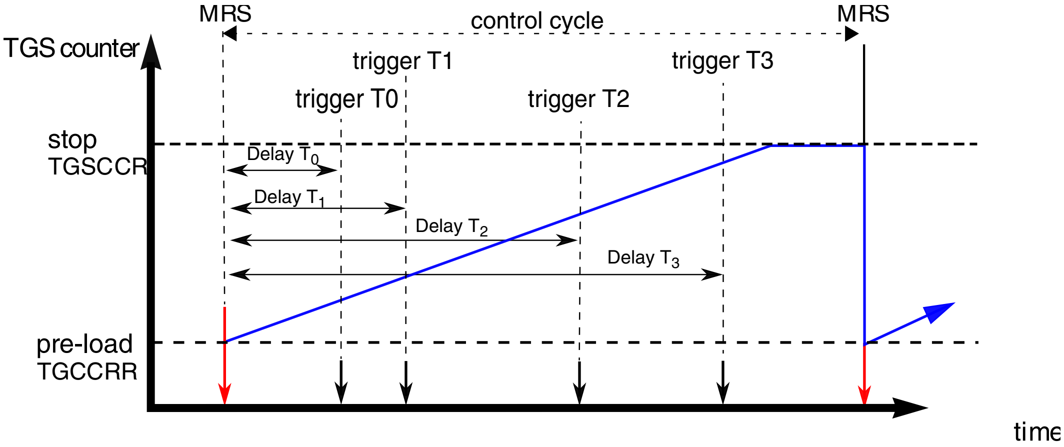

Figure 41-4. Example timing diagram for TGS in triggered mode

41.6.3 TGS in sequential mode

Figure 41-5 shows the blocks and signals related to the TGS in sequential mode.

In sequential mode only one of the 32 input signals is selected by the 5-bit MRS_SM (master reload selection). The selected signal re-loads the trigger list and resets the 3-bit ES counter which selects the trigger event. Sequences of up to eight trigger events are generated in one control cycle.

The 32 input events corresponding to 16 input signals with 2 edges detection per signal are individually enabled through the register TGSISR and OR-ed in order to generate the event signal ES. The ES signal is used to re-load the TGS counter register and to increment the 3-bit ES counter.

Figure 41-5. TGS in sequential mode

Figure 41-6 is a timing diagram for TGS in sequential mode showing the MRS and ES. The trigger events are indicated with the delay with respect to the ES. Note that initially ES and MRS are aligned. The TGS counter is re-loaded on each ES and starts counting up until the next ES or until it matches the value in TGSCCR register and stops.

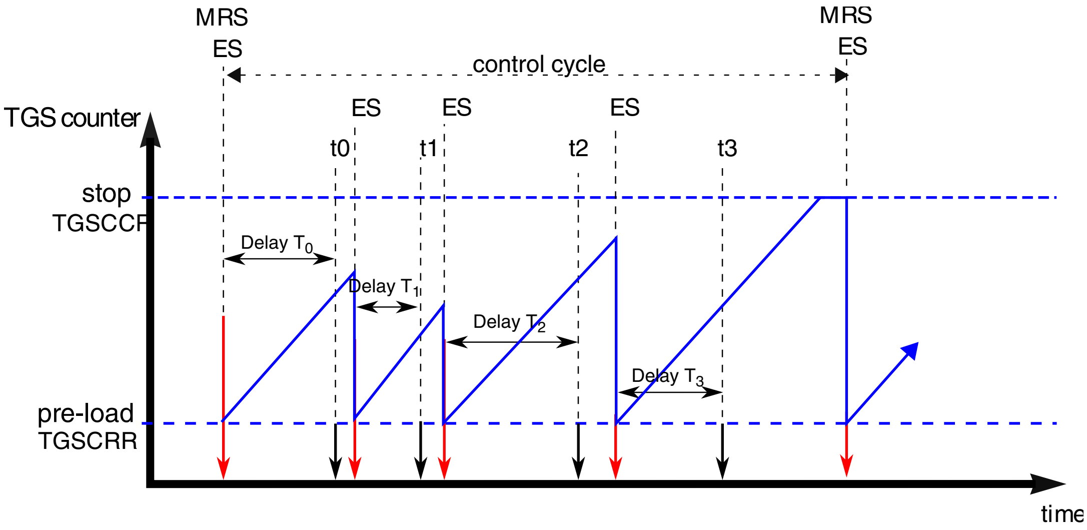

Figure 41-6. Example timing diagram for TGS in sequential mode

41.6.4 TGS counter

The TGS counter counts from negative to positive values as defined by the re-load and stop values defined in register TGSCRR and TGSCCR, respectively. The maximum counter value is 0x7FFF; after that, a counter wrap occurs and the counter value transitions from 0x7FFF to 0x8000. The following figure shows TGS counting examples.

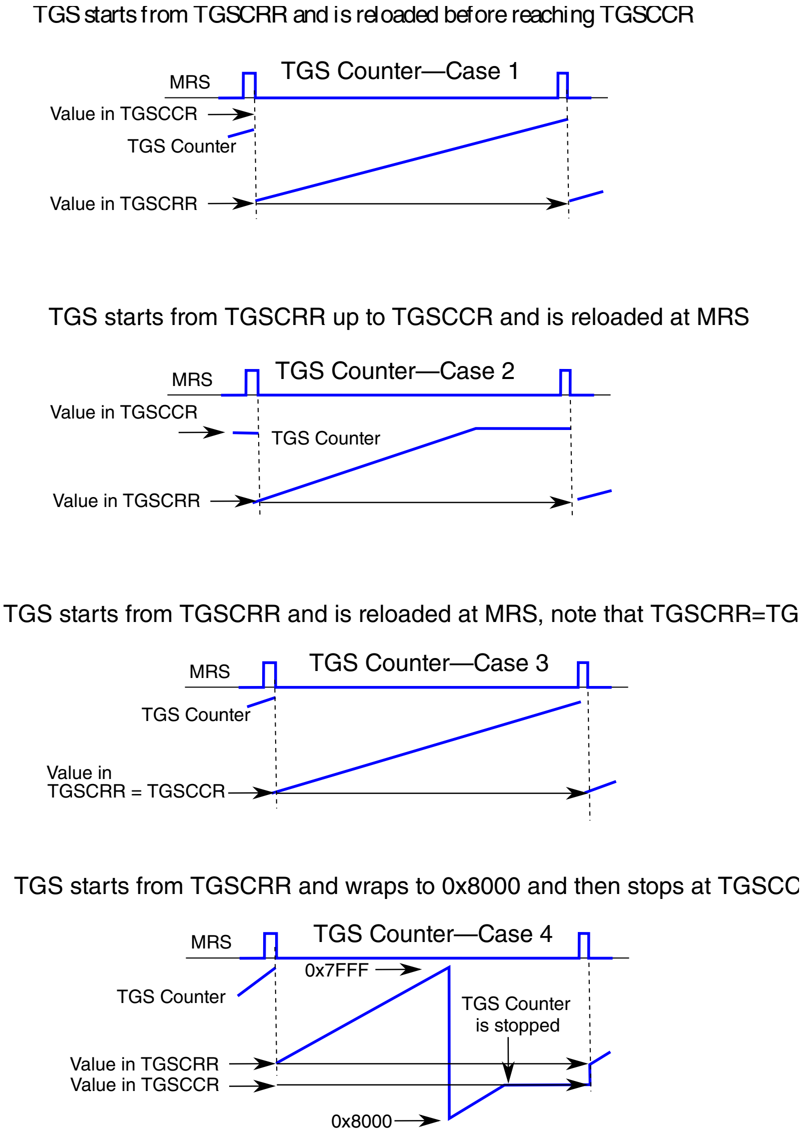

Figure 41-7. TGS counter behavior

Note

The TGS counter starts counting after an MRS and only stops if a counter wrap occurs and TGSCCR value is reached before the next MRS occurs.

41.6.5 Scheduler subunit (SU)

The following figure shows the block diagram of the Scheduler subunit. The SU trigger event outputs are:

1. ADC command or ADC stream of commands
2. eTimer1 pulse
3. eTimer2 pulse
4. External trigger pulse

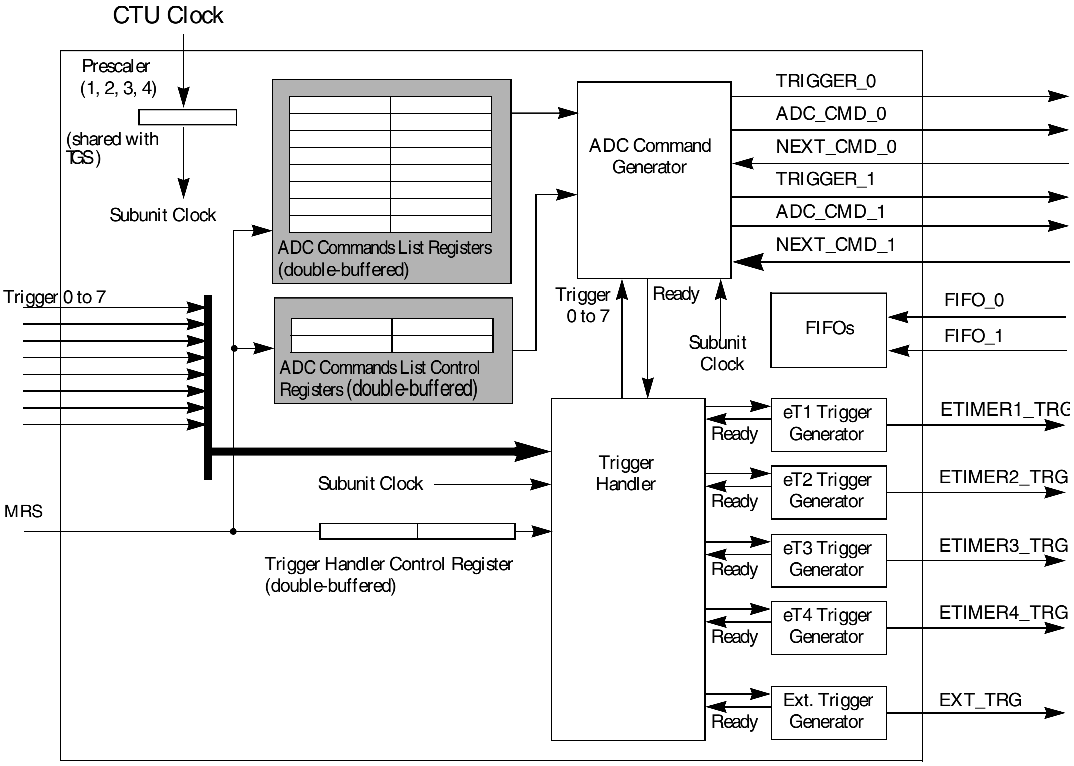

Figure 41-8. Scheduler subunit

The SU receives 8 trigger signals from the Trigger Generator subunit, TGS, and starts a command list to the selected ADC or generates the trigger event outputs. This module has the same functionality in both TGS modes: triggered and sequential. Each of the 4 SU outputs can be linked to any of the 8 trigger events from TGS. This is implemented by the Trigger Handler block. Each trigger event can be linked to one or more SU outputs.

If two events are linked at the same time to the same output (either ADC commands or output triggers) an error is generated and flagged in the EFR register's TnOE bits. In this case, only the trigger with the lowest index is used. For example, if trigger 0 and trigger 1 are linked to the same ADC output and they occur at the same time, an error is generated and the ADC command corresponding to trigger 0 is generated.

When a trigger is linked to an ADC, an associated ADC stream of commands is generated. The ADC Commands List Control Register CLCR1/2 defines the list entry point that is the first command to be executed. Subsequent list pointers are generated in an incremental way as the commands in the list are executed. When a trigger is linked to an eTimer or an EXT_TRG shown in the above figure, an event is generated on the corresponding output. The external trigger output has two modes of operation configured by TGSCR register bit ET_M:

- Pulse mode: a pulse with one system clock width is generated at the output pin
- Toggle mode: the output pin toggles its state as a result of each trigger event

An *ON-Time* and *Guard-Time* are defined for both Pulse and Toggle modes. The COTR register, Control *On-Time* Register, defines the (*ON-Time* + *Guard-Time)* duration. After a trigger has occurred a new trigger will be generated only after (*ON-time* + *Guard-Time)*. The COTR register only applies to external triggers; it does not affect ADC commands.

41.6.6 ADC commands list

The SU implements a command list that stores the ADC commands. The command list stores up to 24 x 16-bit commands (see ADC command list format) in a double-buffered implementation. The command list buffer registers may be updated at any time between two consecutive MRS, but the changes are transferred from the buffers to the actual registers only after an MRS occurs, so a correct reload procedure is performed (see Reload mechanism). The first command in a list is pointed by the 5-bit CLCRx register. Once a command list is triggered, it executes until the last command is found. The last command (n) is defined by the LC bit of the next command (n+1) in the list. Note that the command with LC=1 does not belong to the list and thus it is not executed. Note also that the LC bit is ignored in the first command of a list. See the command list registers, CLR_A_n, CLR_B_n, or CLR_C_n, where n = 1,….,24. The figure below describes the state diagram for the Commands List execution. A sequence of commands on the list is executed until the last command is found. See ADC command list format for more details.

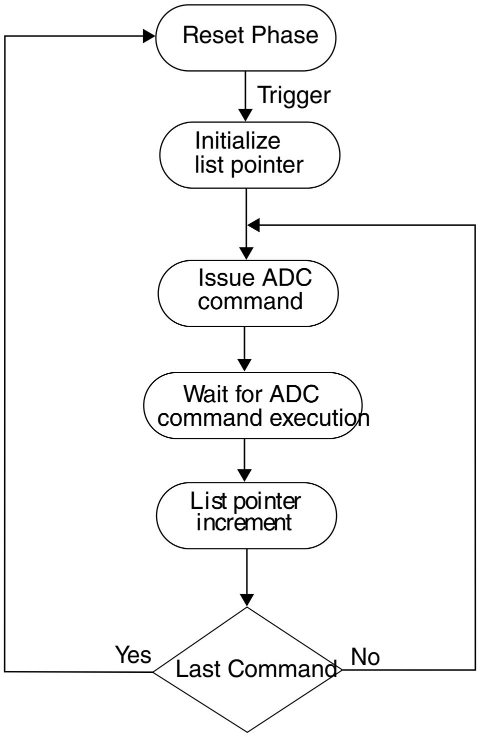

Figure 41-9. ADC command list scanning state diagram

Note

The CTU reads the next command line (the LC bit) to determine if the present command is the last one to be executed.

41.6.7 ADC command list format

The ADC command can be configured for single or dual conversion. In single conversion mode, the command targets one ADC only. In dual conversion mode, the conversion command is sent to both ADCs at the same time. Due to the clock domain crossing between CTU and ADCs, there could be a misalignment of up to one ADC clock cycle between the two commands.

The result of each conversion, in both modes, is stored in one of the four available FIFOs. In dual conversion mode, both ADCs store the result of their conversion in the same FIFO. If both ADCs access the FIFO in the same clock cycle, ADC unit A has higher priority, otherwise the first available conversion result is stored first.

The CTU supports up to 32 channels for both ADCs. The same physical channel cannot be assigned for both ADCs in a dual conversion mode. If there is an attempt to do so, an error is flagged in the EFR register's ICE bit, but the CTU sends the command to both ADCs.

In general, an ADC command is composed by the following fields depending upon the conversion format used (see Commands List Register A for ADC single-conversion mode commands (CTU_CLR_A_*n*)):

- Channel A: ADC A channel number (4 bits)
- Channel B: ADC B channel number (4 bits)
- Target ADC selection: ADC A or ADC B used in single conversion mode only (1 bit)
- FIFO selection bits for the selected ADC unit: up to four FIFOs (2 bits)
- Conversion mode selection: single or dual conversion mode (1 bit)
- Last command (LC): defines the last command in a list (1 bit)
- Interrupt request: enable interrupt request on command execution (1 bit)

The first command of a list is indicated by the CLCR1/2 registers' Tx_INDEX field. The last command is indicated by the LC (Last Command bit) of the following command in the command list. The first command is always executed. The execution of the following commands is controlled by the LC bit.

The figure below describes several scenarios for the command sequencing. If the first command indicated by the CLCR1/2 register is one of the lines identified as "Last command," then the list is a single command list. Note also that the list pointer wraps back to the first command in the list after command 24 is executed and if it is not the last command. If no command is defined as the last command, then the list will be executed continuously in a loop of 24 commands.

- Command List A: two command queues are available with elements 4 and 24 being last commands
- Command List B: sub-list 1 with one single command at address 1, and sub-list 2 with a queue of commands with last command at address 24
- Command List C: sub-list 2 with one single command at address 24, and sub-list 1 with a command queue with last command at address 23
- Command List D: two command queues with a wrap at address 24

Note

> The addresses shown in in the above figure do not represent addresses in the memory map. Please refer to the Memory Map section to check for the actual addresses.

41.6.8 ADC command list operation modes

There are two modes of operation regarding the ADC command list execution: ***streaming*** mode and ***parallel*** mode. In streaming mode, the command lists should behave as a stream of commands, meaning that two or more lists cannot be executed at the same time, but only in a sequence. Thus if list 1 is triggered, it should finish the execution of its last command before list 2 can be triggered. If there is an attempt to trigger more than one list at the same time, then an error occurs.

In parallel mode, up to two lists can be executed at the same time. In order to avoid errors during the execution of two parallel lists, they should not have commands for both ADCs. Therefore, if list 1 has commands for ADC A, then list 2 should only have commands for ADC B. Note also that if a shared analog input is used by one of the lists, it should not be used by the other list in order to avoid a contention and therefore an error. ADC dual conversion commands should also not be used in parallel mode.

Figure 41-11 shows the execution of two lists in streaming mode. While a list is being executed, any attempt to trigger the execution of another list while in this mode will cause an error. Note that both lists may have commands for ADC A or B with no restriction. Also, dual commands may be used.

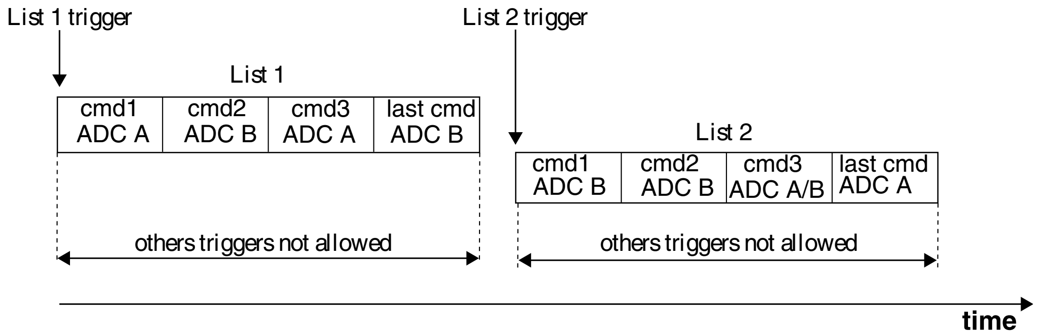

Figure 41-11. List execution in Streaming Mode

Figure 41-12 shows the execution of two lists in parallel mode. There are no restrictions for the triggers of both lists. After the two lists are triggered, no other triggers are allowed. If there is an attempt to trigger a third list while lists 1 and 2 are executing, then an error will be issued by setting ADC_OE bit in EFR register. Note that list 1 only has commands for ADC A and list 2 only has commands for ADC B. Having ADC A and ADC B commands in the same list may cause an error since two commands for the same ADC could be executed from different lists at the same time.

Note

The mixing of commands for both ADCs in the same list in parallel mode must not be used since the correct execution of commands in this case is not guaranteed by the CTU hardware.

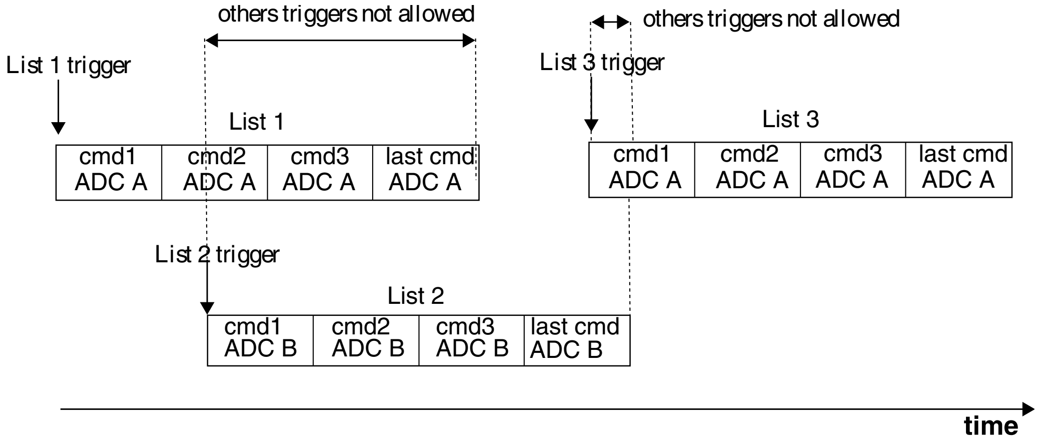

Figure 41-12. List execution in parallel mode

The list mode is controlled by the PAR_LIST bit in the LISTCSR register.

41.6.9 ADC results FIFOs

ADC results are stored in one of the four FIFOs. The FIFOs allow the storage of ADC results according to the type of data acquisition (phase currents, rotor position, ground-noise, and so on) so the software can distinguish data from several ADC channels. Each FIFO has its own interrupt line, DMA request signal, and a status register. The target FIFO for a conversion result is specified in the ADC command. Each FIFO element is 32 bits wide. The following figure shows the FIFO selection for ADC A and ADC B results.

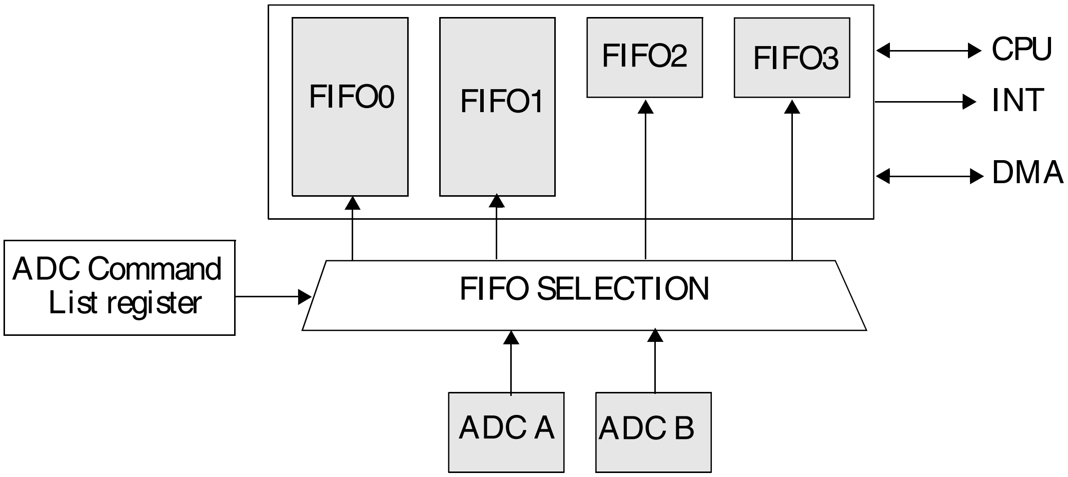

Figure 41-13. FIFO selection for ADC results storage

The CTU FIFOs are fixed depth. For example:

- FIFO0 and FIFO1: 16 entries each, dimensioned for full PWM period current acquisitions
- FIFO2 and FIFO3: 4 entries each, dimensioned for low rate acquisitions

FIFO access can be done by 16-bit or 32-bit read transaction. In 32-bit reads the conversion result, the target ADC, and the channel number are accessed. 8-bit access must not be used; otherwise, the FIFO pointer increments and the complete data is not retrieved. The FIFO result register can be read in a right- or left-aligned format using two different addresses:

- Unsigned right-justified, read from register FLx (for FIFO x)

  (Conversion result is unsigned right-justified data, i.e. bits [11:0] are used for 12-bit resolution and bits [15:12] always return zero)

- Signed left-justified, read from register FLx (for FIFO x)

(Conversion result is signed left-justified data, i.e. bit [15] is reserved for sign and is always read as zero, bits [14:3] are used for 12-bit resolution and bits [2:0] always return zero)

The FIFO access should be based on the status bits in the FCR register. Empty and full indication are provided. If data is read from an empty FIFO, then the read data should not be considered as valid data. Note that there is no indication of an underflow condition. If the FIFO is full and there is an attempt to write more data, then the new data is not written to the FIFO and an overrun flag is set.

41.6.10 Reload mechanism

In order to assure coherent programming, several CTU registers are double-buffered, thus allowing the programming of new data on the buffers while not affecting data being used. All registers are uploaded with buffer data at the same time. For the majority of the CTU registers the re-load is controlled by the Master Reload Signal, MRS.

Since the Master Reload Signal is generated by the hardware, it may occur while the software is still updating the buffer registers. In this case, noncoherent values are written to the registers because the CPU did not finish the programing of all registers. In order to avoid this situation, a General Reload Enable, GRE, control bit is provided. If GRE is cleared then no reload occurs. If this bit is set, then the reload is done when MRS occurs. The GRE bit is automatically cleared by MRS or is cleared by software using the CGRE bit in the same register. The CGRE bit is self-cleared and thus always read as zero.

The software should be able to program all registers buffers within a control cycle. In order to help the software to evaluate that a flawless register programing was executed, the MRS_RE flag is provided in the EFR register. If cleared, this flag indicates that all register buffers were programed before MRS occurred, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programing cycle has initiated.
- Set GRE to indicate that all updates to the buffer registers were performed.
- The reload of all registers is executed when the MRS occurs. Since GRE is set then MRS_RE will not be set.
- GRE and FGRE are cleared when MRS occurs.

See Figure 41-14 for more details.

An error is flagged by MRS_RE when MRS occurs, GRE is cleared, and FGRE is set. This scenario indicates that the software has initiated a register programming but has not finished it before the MRS, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programing cycle has initiated.
- MRS occurs and GRE is not set. In this case MRS_RE is set and, if enabled, an interrupt is generated.
- FGRE is not cleared when MRS occurs and no register is updated, since GRE is cleared.

Note that the software does not need to update all double-buffered registers during a *control cycle*. In order to avoid the error indication it is sufficient to set GRE before a MRS occurs.

A race condition occurs when GRE is being cleared by CGRE at the same time that an MRS occurs. In this case, GRE is considered to be cleared and no reload occurs. Another race condition may occur between CGRE and GRE being set. Since these two bits are in the same register they could eventually be set at the same time. In this case, CGRE has precedence; thus, GRE is cleared.

Note

> MRS has priority over the TGSISR_RE bit in the CR register, which is the re-synchronization bit of the TGSISR.
